Keyword : CO₂ hydrogenation, Ru catalyst, χ -Al₂O₃, ZrO₂-Al₂O₃, TiO₂-Al₂O₃

MISS KANYANAT JEENJUMRAS : SYNTHESIS OF NANOCRYSTALLINE TI AND ZR PROMOTED χ -ALUMINA AND ITS APPLICATION AS THE RU CATALYST SUPPORT FOR CO₂ HYDROGENATION THESIS ADVISOR : ASSISTANT PROFESSOR OKORN MEKASUWANDUMRONG, D.Eng.

Ru/ χ -Al₂O₃ catalysts prepared with various ruthenium precursors by incipient wetness impregnation method were investigated in CO₂ hydrogenation reaction, and the catalysts were characterized by N₂ physisorption, XRD, TEM, H₂ chemisorption and TPR. It was found that Ru/ χ -Al₂O₃ catalyst prepared with ruthenium (III) nitrosyl nitrate (or RNN catalyst) and ruthenium (III) acetylacetonate (or RAA catalyst) precursors exhibited obviously better catalytic activity than Ru/ χ -Al₂O₃ catalyst prepared with hexaammineruthenium (III) chloride precursor (or RCl catalyst). CO₂ conversion of RNN and RAA catalysts were 2 times higher than RCl catalyst and also their CH₄ selectivity were higher than RCl catalyst at all reaction temperatures. In addition, effect of ZrO₂ (5 – 20 wt.%) and TiO₂ (2.5 – 15 wt.%) added into χ -Al₂O₃ support by wet impregnation was also investigated. Compared with Ru/ χ -Al₂O₃ catalyst, Ru/ZrO₂-Al₂O₃ and Ru/TiO₂-Al₂O₃ catalysts exhibited higher CO₂ conversion and CH₄ yield than Ru/ χ -Al₂O₃ catalyst with high active site and Ru dispersion. The addition of large amount of ZrO₂ (20%ZrO₂) and TiO₂ (15%TiO₂) in Ru catalyst could make a higher turnover frequency (TOF) than other of all Ru catalysts.

ACKNOWLEDGEMENTS

First of all, I would like to express my sincere gratitude to my thesis advisor, Asst. Prof. Okorn Mekasuwandumrong who gave knowledge and advice whenever I had a problem of my research and also a problem of my life. In addition, I was grateful for support of Asst. Prof. Tarawipa Puangpetch, Asst. Prof. Worapon Kiatkitipong and Assoc. Prof. Joongjai Panpranot as the chairman and committee of thesis examination.

I would also like to acknowledge all teachers of Chemical Engineering at Silpakorn University. I was gratefully indebted to them for their very valuable comments on this thesis.

Finally, I must express my very profound thankful to my parents and my friends for providing me with support, encouragement and assistance. This accomplishment would not have been possible without them.

Kanyanat JEENJUMRAS

CHAPTER I

INTRODUCTION

1.1 Motivation

In the last century, concentration of CO₂ in the atmosphere has increased consecutively, resulting from power generation with fossil fuels, activities of industry and deforestation. The recording of CO₂ content in the atmosphere has increased from ~280 ppm before the development of industry to ~390 ppm in 2010 and then, is predicted that it further increased to 570 ppm by the end of the century. The increase of CO₂ emission has created concerns about the increasing of global temperature and climate change due to the greenhouse effect, which has CO₂ as an important component. Therefore, finding methods to reduce the amount of CO₂ in the atmosphere is very interesting and urgent necessary. There are 3 possible strategies presented, that are reduction of CO₂ produced, CO₂ sequestration and utilization of CO₂ [1].

The converting of CO₂ into hydrocarbon product such as methane (CH₄) has received interesting option due to the use of CO₂ captured from natural gas and other sources, combined with H₂ generated from electrolysis of water using renewable electrical energy. It is possible to upgrade CO₂ to useful CH₄ or synthetic natural gas (SNG) [2]. CH₄ can be produced energy through combustion. Moreover, CO₂ released from the production of energy can be recycled into CH₄ by hydrogenation of CO₂.

Many catalysts found in several researches of CO₂ hydrogenation are Ni, Ru, Rh, Pd, Co, Fe, Cu and etc. deposited on various supports (e.g., SiO₂, TiO₂, Al₂O₃, ZrO₂, and CeO₂) [1, 3]. Among all the catalysts, Ru-based catalyst is the most effective noble metal and the most stable when operated in a wide conditions range [3, 4]. However, the activity of Ru-based catalyst depends on the properties of the support.

Alumina (Al_2O_3) is normally used as catalyst and/or support due to its excellent thermal stability, fine particle size and high surface area. In addition, the high stable χ - Al_2O_3 can be prepared with common technique, by calcination of microcrystalline gibbsite [5, 6].

Zirconia (ZrO_2) possesses high surface area, high thermal stability and appropriate in hydrogenation of CO_2 [7]. Titania (TiO_2) is high activity and the most effective when supported Ru catalyst in CO_2 hydrogenation. Moreover, TiO_2 - Al_2O_3 enhances activity of catalyst which is higher surface area and thermal stability than the titania or alumina alone [8].

In this research, the activity of Ru supported on χ - Al_2O_3 , TiO_2 - Al_2O_3 and ZrO_2 - Al_2O_3 catalysts is performed in CO_2 hydrogenation reaction. The χ - Al_2O_3 support is obtained by thermal decomposition of gibbsite. The effect of Ru precursors of Ru/ χ - Al_2O_3 is also investigated. The two binary oxides supports are prepared by using wet impregnation method. Moreover, the effect of TiO_2 and ZrO_2 content in χ - Al_2O_3 supported Ru catalysts on the physiochemical and catalytic properties are also investigated. The characterization of these catalysts are performed using X-ray diffraction (XRD), N_2 physisorption (BET), H_2 chemisorption, temperature programmed reduction (TPR) and transmission electron microscope (TEM) techniques.

1.2 Objective of Research

The objective of this research is to study the effect of TiO_2 - Al_2O_3 and ZrO_2 - Al_2O_3 on the physiochemical properties and catalytic performance of supported Ru catalysts in CO_2 hydrogenation reaction.

1.3 Scope of Research

1.3.1 Catalytic preparation

1) The Ru/ χ -Al₂O₃ catalysts used in this research were prepared by incipient wetness impregnation method by using 3 different ruthenium precursors and Ru loading content was fixed at 1 wt.%.

2) The TiO₂-Al₂O₃ and ZrO₂-Al₂O₃ supports were prepared by using wet impregnation method. The content of binary oxides support was varied as 5 wt.%, 10 wt.% and 15 wt.% of TiO₂ or ZrO₂ and all supports were impregnated with the best Ru precursor from 1).

1.3.2 Catalytic activity test

The activity test of catalysts was performed by CO₂ hydrogenation reaction and operated with temperature programmed reaction method at atmospheric pressure.

1.3.3 Catalytic characterization

The characterization of catalysts was determined by various techniques, including:

- 1) X-ray diffraction (XRD)
- 2) N₂ physisorption (BET)
- 3) H₂ chemisorption
- 4) Temperature programmed reduction (TPR)
- 5) Transmission electron microscope (TEM)

1.4 Contribution of Research

1.4.1 Reduce carbon dioxide concentration in atmosphere, which is the cause of greenhouse effect.

1.4.2 Produce methane from CO₂ hydrogenation with χ -Al₂O₃ and binary oxides (TiO₂-Al₂O₃, ZrO₂-Al₂O₃) supported Ru catalysts.

1.4.3 Prepare Ru/ χ -Al₂O₃, Ru/TiO₂-Al₂O₃ and Ru/ZrO₂-Al₂O₃ by using incipient wetness impregnation method.

CHAPTER II

THEORY

2.1 CO₂ hydrogenation

Hydrogenation of CO₂ is an one of interesting option for reduction of greenhouse gases [9]. CO₂ can react with hydrogen to production of valuable chemicals and fuels. The main products in this reaction process can be classified into two groups as chemicals and fuels, which illustrated in **Figure 1** [1, 10].

Figure 1 Product species formed from CO₂ hydrogenation process [1].

In CO₂ hydrogenation to methane, it can be called as CO₂ methanation or the Sabatier reaction. The reacted CO₂ with hydrogen can produce syngas and compressed natural gas as methane. This reaction was developed from work of NASA (National Aeronautics and Space Administration) to application of oxygen reclaiming within life support system. CO₂ in cabin atmosphere is combined with hydrogen to obtain methane and water vapor. Which stored water is used in electrolysis process to produce breathing oxygen [1, 11].

The CO₂ methanation equation is shown in Eq. (1) [3, 12].

2.2 Ruthenium

Ruthenium (Ru) is one of platinum group metals (PGMs) [13, 14]. It is silvery-grey, shiny metal that looks like platinum. Ruthenium is of the rarest metals in the world. It is harder and more brittle than platinum [14-16]. It is better thermal resistance due to its high melting point as 2,333°C and boiling point as 4,147°C [15, 17]. Ruthenium is not tarnish at room temperature, but can oxidize explosively in air at about 800°C [14, 17]. Other properties of ruthenium are shown in **Table 1** [15, 16].

Because of ruthenium is very hard, it is used as an alloying agent to harden platinum, palladium and other metals in platinum group. Adding ruthenium-hardened alloying agent in platinum and palladium are made for the manufacture of fine jewelry and of electric contacts that extremely wear resistance [14-17]. Ruthenium is high resistance to chemical attack therefore it is used for improving corrosion resistance of titanium by addition of 0.1% Ru [14, 17]. Ruthenium is also versatile catalyst. It is used in removal of H₂S from oil refineries and other industrial processes [14, 17]. It can be catalyst in CO₂ hydrogenation processes to methanol and methane [3, 18].

Table 1 Chemical and physical properties of ruthenium [15, 16].

Ruthenium properties	
Atomic number	44
Molecular weight	101.07
Melting point	2,333°C
Boiling point	4,147°C
Density (g/cm ³)	12.1

2.3 Aluminum oxide

Aluminum oxide also called alumina is chemical equation as Al_2O_3 that is a white or colorless crystalline structure [19]. Its melting point is 2,050°C and its boiling point is 3,500°C [20]. Alumina structure consists two types of sites that is hexagonal and octahedral [21]. The crystalline alumina structures have many different forms which these alumina structure were called as “Transition Alumina” and used Greek alphabet denote the different alumina forms such as chi, kappa, alpha, gamma, theta and rho etc. The different alumina structures can be occurred by five alumina hydroxides: gibbsite, boehmite, beyerite, diaspore and nordstrandite that used as starting structure. The transition alumina is illustrated in **Figure 2** which it depend on thermal transformation [22].

Figure 2 Alumina hydroxides transformation relate with temperature [22].

In the present, alumina is very interesting due to it is broadly application such as adsorbents, coatings, filters, protective barriers, electronic-device fabrication, soft abrasives, ceramics, catalysts and catalyst supports [22-24]. Moreover, 90% of all alumina produced is used in aluminum production. These application indicate the properties of alumina very well that are high thermal stability, low electric conductivity, high resistance to chemical corrosion, high strength and also extreme material hardness—diamond is only harder than alumina [19, 21, 23].

2.4 Zirconium dioxide

Zirconium dioxide (ZrO_2) is also called zirconium oxide or zirconia. It is one of the most use as ceramic materials [25]. Application of zirconium dioxide consists ceramic pigments, artificial jewelry, dental bridges and crowns, fuel cell membranes, joint implants, insulator and fire-retardant materials [25, 26]. It is also used as catalyst supports [27]. Zirconium dioxide has specific properties that is non-magnetic, high acid resistance, low reactivity, great hardness, and excellent thermal stability. It cannot be melted at temperature below 2,680°C. Since its high melting point, it is

the oldest mineral found on the earth [25, 28]. Chemical and physical properties are exposed in **Table 2** [25, 26, 29]. In addition, characteristics of zirconium dioxide is illustrated in TEM image which it shown in **Figure 3** [25].

Table 2 Chemical and physical properties of zirconium dioxide [25, 26, 29].

Zirconium dioxide properties	
Chemical formula	ZrO ₂
Molecular weight (g/mol)	123.22
Melting point	2,680°C
Boiling point	4,300°C
Density (g/cm ³)	5.68

Figure 3 TEM image of zirconium dioxide [25].

Zirconium dioxide phase transformation depend on various temperatures that follows in below [28, 30]:

Monoclinic phase is the most stable of zirconium dioxide at low temperature. At temperature of $1,170^\circ\text{C}$ and ambient pressure, tetragonal phase becomes to be transformed and then, it is transformed to cubic phase at $2,370^\circ\text{C}$ [28, 30, 31]. Structural model of three zirconium dioxide phases is indicated in **Figure 4** [31].

Figure 4 Structural model of zirconium dioxide: monoclinic (A), tetragonal (B) and cubic (C) [31].

2.5 Titanium dioxide

Titanium dioxide (TiO₂) is generally known as titania. It is a white, opaque and resists to UV radiation. Since its UV resistance, it is added in cosmetic products such as sunscreen creams, whitening creams, etc. [32, 33]. Other application of titanium dioxide is an additive in paints, coatings, ceramics, filter for polymers, luminescent materials, solar cells and also catalysts [33-35]. **Table 3** is exhibited chemical and physical properties of titanium dioxide [33, 36].

Table 3 Chemical and physical properties of titanium dioxide [33, 36].

Titanium dioxide properties	
Chemical formula	TiO ₂
Molecular weight (g/mol)	79.87
Melting point	1,843°C
Boiling point	2,972°C
Density (g/cm ³)	4.23 (rutile) 3.78 (anatase)

Titanium dioxide is used as heterogeneous catalysts such as in CO₂ methanation reaction—it is the most efficient support in Ru catalyst, and in the Deacon reaction [37]. In addition, titanium dioxide is utilized in environmental and photocatalytic for hydrogen production by water splitting, and treatment of polluted air and wastewater [34, 38, 39]. Nowadays, TiO₂ nanostructure can be synthesized by several methods such as sol-gel, hydrothermal, solvothermal, direct oxidation, electrodeposition, microwave methods, etc. [40].

Titanium dioxide has three different polymorphs that consists rutile (tetragonal), anatase (tetragonal) and brookite (orthorhombic). Rutile is only stable form at all temperatures and pressures, whereas, anatase and brookite are metastable and they can be transformed to rutile when heated. This transformation to rutile cannot identify a unique temperature [34, 35, 41, 42]. The crystal structures of rutile, anatase and brookite are shown in **Figure 5** [43, 44].

Figure 5 Crystal phases of rutile (A), anatase (B) and brookite (C) [43, 44].

CHAPTER III

LITERATURE REVIEWS

3.1 Chi-alumina (χ -Al₂O₃)

Alumina is considered to be one of the most interesting materials because of its special chemical, physical and catalytic properties, besides it is excellent thermal stability with high melting point as 2,050°C. Thereby, the alumina have used extensively such as ceramics, ceramic coating, protective barriers, wear-resistance materials, filters, crucibles, absorbents, catalysts, catalyst supports and soft abrasives [5, 20-24]. The alumina can be produced from five crystalline aluminum hydroxide precursors that consists bayerite, nordstrandite, diaspore, gibbsite and boehmite. These alumina precursors can be transformed to various metastable structures which the structures of each alumina depend on temperature of transition [22, 24]. Several alumina research commonly used gibbsite as alumina precursor. The transition of alumina structures from gibbsite is separated to two routes: [6, 45, 46]

A. Tonejc et al. [46] used gibbsite as starting material for transformation to α -Al₂O₃. They found that the gibbsite could transform to χ -Al₂O₃ when heated at 500°C, κ -Al₂O₃ at 800°C and α -Al₂O₃ at 1,300°C. Chang P.-L. et al. [45] also said that gibbsite was heating treatment for produce χ -Al₂O₃ at 600°C then χ -Al₂O₃ was transformed to κ -Al₂O₃ at 1,000°C and κ -Al₂O₃ was formed as α -Al₂O₃ at 1,150-1,300°C. So that κ -Al₂O₃ is intermediate in formation of $\chi \rightarrow \alpha$ -Al₂O₃ reaction. In addition, the alumina transition in route 1 (χ -, κ -, α -alumina) can be occurred by thermal decomposition of fine-grained gibbsite in air, whereas coarse-grained gibbsite can be transformed to

boehmite with water vapor presence or hydrothermal method and then metamorphose as γ -, δ -, θ -, α -alumina with various temperature [24, 47].

χ -Al₂O₃ is interested as catalysts and catalyst supports in several chemical reactions. Chaitree W. et al. [5] studied effect of χ -Al₂O₃ on the catalytic behavior of Co/Al₂O₃ in CO hydrogenation which χ -Al₂O₃ was prepared by thermal decomposition (χ -GB) and solvothermal method (χ -SV). They found that %Co metal dispersion of Co/ χ -GB was higher than Co/ χ -SV and Co/ γ -Al₂O₃ respectively (Co/ χ -GB > Co/ χ -SV > Co/ γ -Al₂O₃). Moreover, the Co/ χ -GB and Co/ χ -SV were higher CO conversion (both in initial and steady state), CH₄ selectivity and turnover frequency (TOF) than Co/ γ -Al₂O₃. Kanazaki E. et al. [48] reported that Pd/CeO₂ supported on χ -Al₂O₃ catalyst gave excellent catalytic activity in methane oxidation reaction. Janlamool J. et al. [49] studied composition effect of χ -Al₂O₃ and γ -Al₂O₃ catalyst in ethanol dehydration to ethylene. Their results indicated that catalytic activity decreased in order as 50% χ -Al₂O₃ > 100% χ -Al₂O₃ > 70% χ -Al₂O₃ > 0% χ -Al₂O₃ at reaction temperature of 200-300°C. Observing, both catalyst mixed with χ -Al₂O₃ in γ -Al₂O₃ (70% χ -Al₂O₃ and 50% χ -Al₂O₃) and pure χ -phase alumina catalyst (100% χ -Al₂O₃) were higher catalytic conversion than pure γ -phase alumina catalyst (0% χ -Al₂O₃) at reaction temperature of 200°C. Moreover, they concluded that hexagonal close packing (hcp) of χ -Al₂O₃ structure was better catalytic conversion and ethylene yield than cubic close packing (ccp) of γ -Al₂O₃ structure. In other research, studying effect of phase composition between γ - and χ -Al₂O₃ on Pt/Al₂O₃ catalyst in CO oxidation by Meephoka C. et al. [23]. The Pt/Al₂O₃ catalysts mixed of γ - and χ -Al₂O₃ (30 - 70% χ -Al₂O₃) were higher CO conversion than without χ -Al₂O₃ catalyst whereas Pt supported on 10% χ -Al₂O₃ catalyst indicated the worst its activity. In addition, the CO oxidation activities related to amount of Pt active sites. It concludes that the χ -Al₂O₃ is interesting for used as catalyst and catalyst support. Therefore, in this research, the χ -Al₂O₃ is used as catalyst support.

3.2 CO₂ hydrogenation reaction

In present, CO₂ in atmosphere is continuously increased because expanding of world's population and industry growth, that causing global warmed up through the greenhouse effect. Therefore, reduction of CO₂ in atmosphere is urgently necessity. In several strategies. CO₂ hydrogenation to methane or CO₂ methanation is an option of Carbon Capture and Sequestration (CCS), that is capture of CO₂ in atmosphere and storage in underground. After that the CO₂ captured is utilized and converted to methane or chemical compounds [8, 9, 50]. The CO₂ methanation reaction (Eq. (1) in chapter II) is strongly exothermic, although thermodynamics favor at low temperatures. From this reason, catalyst used in the CO₂ methanation reaction should be high activity catalysts at low temperatures and enough stable to high temperatures [8].

CO₂ hydrogenation to methane is considered by using several metal catalysts, including Ni, Ru, Rh, Pt, Pd, Ir, Co and Fe carried out on various oxide supports (e.g. TiO₂, Al₂O₃, SiO₂, CeO₂, ZrO₂, MgO) [8, 12, 51, 52]. Catalysts of 3% Ru/Al₂O₃ and 20% Ni/Al₂O₃ were studied in carbon dioxide methanation reaction by Garbarino G. et al. [9]. Feed gases were mixed with 6%CO₂ and 30% H₂ diluted with 64% N₂. The catalysts were reacted with increasing temperature from 523 to 773 K and step back to 523 K. They reported that CO₂ conversion of Ru/Al₂O₃ was almost zero at low temperature (523 – 573 K), then CO₂ conversion and CH₄ yield increased at 623 - 673 K that was effect of conditioning. Moreover, CO₂ conversion and CH₄ yield in decreasing temperature steps were higher than in increasing step at same temperature. These results confirmed that the conditioning affected to activities of catalysts. In addition, CO₂ conversion and CH₄ yield of Ni/Al₂O₃ was clearly lower than that of Ru/Al₂O₃, concluding that Ru/Al₂O₃ catalyst was more active than Ni/Al₂O₃ catalyst. Activities of Ru and Ni supported on SiO₂ catalysts in CO₂ methanation reaction were studied by Fujita S.-I. et al. [53]. CO₂ conversion of 5.0 wt.% Ru/SiO₂ was higher than that of 8.2 wt.% Ni/SiO₂ as 3.2% and 1.0%,

respectively. The same results considered in rate of methane formation, the methane formation rate of Ru/SiO₂ was obviously more than that of Ni/SiO₂ as 26.2 and 8.2 $\mu\text{mol/g}_{\text{cat.}}/\text{min}$. Panagiotopoulou P. [51] reported results of noble metals (as Rh, Ru, Pt and Pd) supported on TiO₂ catalysts in CO₂ hydrogenation reaction. Mixed gases of 5%CO₂ and 20%H₂ in He were used as feed gases. CO₂ conversion of Rh/TiO₂ catalyst was clearly higher than other catalysts and reached to equilibrium at about 380°C that shown in **Figure 6** in Ru/TiO₂ and Pt/TiO₂ catalysts. CO₂ conversion curves were shift to higher temperature, whereas the CO₂ conversion of Pd/TiO₂ catalyst was less than 10% albeit reaction temperature reached 440°C. In addition, methane selectivity at reaction temperature of 350°C decreased following the order of Rh > Ru > Pt > Pd, indicated that the reverse water gas shift (RWGS) reaction was strongly supported over Pt and Pd catalysts which it produced co-production compound of CO.

Figure 6 CO₂ conversion in a function of reaction temperatures (A), CH₄ selectivity and CO at reaction temperature of 350°C (B) [51].

Li D. et al. [54] studied Ru/TiO₂ catalysts prepared by different methods and Ru loading. In the same condition, initial rate and TOF of Ru/TiO₂ catalysts prepared by spray reaction (SPR) method were higher than those of Ru/TiO₂ catalysts prepared by impregnation (IMP) method. The spr-Ru/TiO₂ catalysts were supported by

characteristic of fine particles and new active sites creation at interface. Similarly, Ru/Al₂O₃ catalysts prepared by three different methods were studied by Li D. et al. [4]. The three preparation methods were consisted spray reaction (SPR), impregnation (IMP) and Hybrid (HYB) method—method of combination with spray and impregnation. The initial rate and TOF of Ru/Al₂O₃ catalysts indicated in decreasing order as spr-Ru/Al₂O₃ > imp-Ru/Al₂O₃ > hyb-Ru/Al₂O₃ catalyst. The initial rate and TOF of spr-Ru/Al₂O₃ catalyst was 2 times and 3 times higher than imp-Ru/Al₂O₃ catalyst, respectively. Reasons of the higher activities of spr-Ru/Al₂O₃ catalyst probably were its fine particle structure and homogeneity of metal and support. In addition, Li D. et al. [4] also studied impact of amount of Ru molar loading as 1%, 5%, 10% and 15% in spr-Ru/Al₂O₃ catalysts. The 5 mol% of Ru/Al₂O₃ catalyst could get the maximum initial catalytic rate and hydrogen uptake. It was concluded that the amount of Ru metal in catalyst influenced on catalytic activity per site. Kwak J.H. et al. [55] reported effect of Ru content as 0.01, 0.5, 1, 2 and 5 wt.% supported on Al₂O₃ catalysts which exhibited in **Figure 7** Catalyst 5 wt.% Ru/Al₂O₃ showed the maximum CO₂ conversion at reaction temperature of ~320°C. In decreasing amount of Ru loading, CO₂ conversion curves were shifted toward higher temperature. Interesting, CO₂ conversion of all Ru loading catalysts continuously increased and then, dropped to above ~450°C, although the amount of loading changed by a factor of 50. Whereas, CO formation profiles were quiet different and lower Ru loading catalysts were significantly higher CO rate at low temperature. Moreover, CH₄ yield increased with increasing Ru loading and temperature of maximum CH₄ yield was shift to higher temperature. From these reports, they concluded that CH₄ formation was favored in large metal clusters catalyst because CH₄ formation increased with increasing amount of Ru loading.

Figure 7 CO₂ hydrogenation reaction on Ru/Al₂O₃ catalyst in a function of temperature: CO₂ conversion (A), CO yield (B) and CH₄ yield (C) [55].

Supports influence to catalytic properties that consists three main features: improving of catalyst dispersion, reducing of inactive spinel phase formation, and modifying of catalytic reducibility [27]. Iizuka T. et al. [52] investigated CO₂ hydrogenation reaction over Rh catalysts supported on various metal oxides as ZrO₂, Al₂O₃, SiO₂ and MgO. The Rh/ZrO₂ indicated highest activity at all reaction

temperatures and the lowest activity was Rh/MgO. The activity of all catalysts was showed in order as $\text{Rh/ZrO}_2 > \text{Rh/Al}_2\text{O}_3 > \text{Rh/SiO}_2 > \text{Rh/MgO}$. Suo Z.-h. et al. [56] studied 5 wt.% Fe supported on TiO_2 , ZrO_2 and Al_2O_3 catalysts in CO_2 hydrogenation. Reduction of catalytic activity was followed in order of $\text{Fe/TiO}_2 > \text{Fe/ZrO}_2 > \text{Fe/Al}_2\text{O}_3$. The Fe/TiO_2 gave higher CO_2 conversion (19%) and also better selectivity of C_{2+} -hydrocarbon. In addition, binary metal oxide supports were investigated in several researches. Rynkowski J.M. et al. [57] studied effect of $\text{CeO}_2\text{-Al}_2\text{O}_3$ binary oxide supported Ru catalysts in CO_2 methanation. 5 wt% Ru catalysts were varied CeO_2 content in $\text{CeO}_2\text{-Al}_2\text{O}_3$ as 10, 20 wt% CeO_2 . The maximum conversion of all catalysts were followed as $\text{Ru/20CeO}_2\text{80Al}_2\text{O}_3 = 76\%$, $\text{Ru/10CeO}_2\text{90Al}_2\text{O}_3 = 74.5\%$ and $\text{Ru/Al}_2\text{O}_3 = 72\%$. Observing, adding CeO_2 in catalyst support gave higher activity and lower reaction temperature of maximum conversion than without CeO_2 in catalyst support. Xu J. et al. [8] interested in catalysts of binary oxide support too. They used 5 wt.% Ru catalysts supported on 5, 10, 15 wt.% TiO_2 in Al_2O_3 which those catalyst supports were compared with $\text{Ru/Al}_2\text{O}_3$ catalyst. CO_2 conversion as a function of reaction temperature was observed that the Ru catalysts with loading of TiO_2 were higher CO_2 conversion than $\text{Ru/Al}_2\text{O}_3$ catalyst that shown in **Figure 8**. At reaction temperature of 225°C , reaction rate of $\text{Ru/5 wt\% TiO}_2\text{-Al}_2\text{O}_3$ catalyst ($0.59 \text{ molCO}_2\text{/gRu}\cdot\text{h}$) was 3.1 times higher than that of $\text{Ru/Al}_2\text{O}_3$ ($0.19 \text{ molCO}_2\text{/gRu}\cdot\text{h}$) catalyst. Moreover, loading of TiO_2 in catalysts could inhibit the aggregation of RuO_2 on catalyst surface.

Figure 8 CO₂ conversion of various TiO₂ loading in TiO₂-Al₂O₃ binary oxide supported Ru catalysts [8].

CHATER IV RESEARCH METHODOLOGY

4.1 Materials Preparation

4.1.1 Materials

The chemicals used in the catalytic preparation are shown in **Table 4**.

Table 4 The chemicals were prepared for synthetic of catalysts.

Chemical	Formula	Grade	Manufacture
Ruthenium (III) acetylacetonate	Ru(C ₅ H ₇ O ₂) ₃	97%	Sigma-Aldrich
Ruthenium (III) nitrosyl nitrate solution	Ru(NO)(NO ₃) _x (OH) _y , x + y = 3	1.5% in nitric acid	Sigma-Aldrich
Hexaammineruthenium (III) chloride	Ru(NH ₃) ₆ Cl ₃	98%	Sigma-Aldrich
Gibbsite	Al(OH) ₃	Technical	Sigma-Aldrich
Titanium (IV) butoxide	Ti(OCH ₂ CH ₂ CH ₂ CH ₃) ₄	97%	Sigma-Aldrich
Zirconium n-butoxide	C ₁₆ H ₃₆ O ₄ Zr	80% in 1-butanol	Alfa Aesar
Xylene	C ₈ H ₁₀	AR	QReC

4.1.2 Support preparation

The chemical properties used in the preparation of support are shown in **Table 4**. The χ - Al_2O_3 support was prepared by the thermal decomposition of microcrystalline gibbsite. The gibbsite was calcined at 600°C in tube furnace under the air flow (100 ml/min) with heating rate of 10°C/min and was hold in this temperature for 4 hours.

TiO_2 - Al_2O_3 and ZrO_2 - Al_2O_3 binary oxides supports were prepared using wet impregnation method. The content of TiO_2 in Al_2O_3 was varied as 5 wt.%, 10 wt.%, 15 wt.% and 20 wt.%, and the content of ZrO_2 in Al_2O_3 was varied as 2.5 wt.%, 5 wt.%, 10 wt.% and 15 wt.%. In the case of TiO_2 - Al_2O_3 support, gibbsite was added in titanium (IV) butoxide diluted with xylene solvent. Then, the sample was heated up to 80°C and hold in this temperature until the sample was dampened. After that, the sample was dried at 110°C for 12 hours and calcined in air (100 ml/min) by heating up to 600°C with rate 10°C/min for 4 hours. The ZrO_2 - Al_2O_3 support was prepared with the same preparation procedure but zirconium n-butoxide was used as a precursor instead.

4.1.3 Catalytic preparation

χ - Al_2O_3 supported Ru catalysts was prepared by incipient wetness impregnation method with 1 wt.% of Ru loading. The Ru precursors of catalyst were varied with 3 different Ru precursors, which included ruthenium (III) acetylacetonate, ruthenium (III) nitrosyl nitrate solution and hexaammineruthenium (III) chloride. The support was impregnated with Ru precursor dissolved in solvent and kept at room temperature for 6 hours. Then, the sample was dried at 110°C for 12 hours and calcined in air (100 ml/min) at 300°C with heating rate of 10°C/min at 300°C and hold in this temperature for 4 hours. The details of catalytic preparation precursor used for Ru/ χ - Al_2O_3 catalysts are shown in **Table 5**.

This preparation procedure was used also to prepare $\text{TiO}_2\text{-Al}_2\text{O}_3$ and $\text{ZrO}_2\text{-Al}_2\text{O}_3$ binary oxides supported Ru catalysts. But, the Ru precursor used for preparation of $\text{Ru/TiO}_2\text{-Al}_2\text{O}_3$ and $\text{Ru/ZrO}_2\text{-Al}_2\text{O}_3$ catalysts was chose from the best of $\text{Ru}/\chi\text{-Al}_2\text{O}_3$ catalysts.

Table 5 The details of preparation precursors of $\text{Ru}/\chi\text{-Al}_2\text{O}_3$ catalysts.

Support	Ru precursor	Solvent
$\chi\text{-Al}_2\text{O}_3$	Ruthenium (III) acetylacetonate	Xylene
	Ruthenium (III) nitrosyl nitrate solution	Deionized Water
	Hexaammineruthenium (III) chloride	Deionized Water

4.2 Catalytic activity test

The catalytic activity test was performed by CO_2 hydrogenation reaction. In addition, the flow diagram of this system is shown in **Figure 9**.

Figure 9 The flow diagram of operating system of CO₂ hydrogenation.

The activity test of the catalysts in CO₂ hydrogenation reaction was performed in a continuous-flow fixed-bed reactor with the inner diameter of 7.1 mm (stainless steel) under atmospheric pressure. 0.15 ml of catalyst powder was loaded in reactor, and then, reduced in H₂ with 30 ml/min at 400°C for 2 hours before starting the reaction. The reaction was carried out using temperature programmed reaction method (250, 275, 300, 325, 350, 375, 400 and 425°C), which increased continuously by 25°C per hour. The gas mixture of H₂/CO₂ = 3 and balanced with helium (CO₂+H₂ = 20 ml/min and He = 20 ml/min) was used as the feed gases for reaction with the catalysts prepared by different Ru precursors. In addition, H₂/CO₂ = 4 balanced with helium (CO₂+H₂ = 20 ml/min, H₂ = 5 ml/min and He = 15 ml/min) as feed gas were used for the reaction of Ru/ZrO₂ and Ru/TiO₂ catalysts. GHSV used in the reaction was at 14,000 h⁻¹. The gas products out of the reactor were measured by using gas chromatograph (SHIMADZU GC-14B) with a TCD and FID detector. The operating conditions of GC-TCD and GC-FID detectors are shown in **Table 6** and **Table 7**, respectively.

Table 6 The operating conditions of GC-TCD detector used for catalytic activity test.

Gas chromatograph	SHIMADZU GC-14B
Detector	TCD
Column	Porapack Q
Carrier gas	He
Carrier gas flow	30 ml/min
Injector temperature	150°C
Detector temperature	150°C
Column temperature	40°C

Analysis gas	CO ₂ , CO, CH ₄
--------------	---------------------------------------

Table 7 The operating conditions of GC-FID detector used for catalytic activity test.

Gas chromatograph	SHIMADZU GC-14B
Detector	FID
Column	DB-1
Carrier gas	N ₂
Split flow rate	40 ml/min
Purge flow rate	10 ml/min
Carrier pressure	40 kPa
Make up pressure	50 kPa
Injector temperature	200°C
Detector temperature	200°C
Column temperature	40°C
Analysis gas	Hydrocarbons

4.3 Catalytic characterization

In this research, the characterization of catalysts was determined using techniques of X-ray diffraction (XRD), N₂ physisorption (BET), H₂ chemisorption, Temperature programmed reduction (TPR) and Transmission electron microscope (TEM).

4.3.1 X-ray diffraction (XRD)

X-ray diffraction (XRD) is a technique that used to study crystalline structure of catalysts. XRD patterns were recorded using a Siemens D5000 X-ray diffractometer and Cu $K\alpha$ radiation with a Ni filter. The range of 2θ was from 20° to 80° . The crystallite size was calculated using Scherrer's equation.

4.3.2 N_2 physisorption (BET)

The specific surface area, average pore size and pore volume of catalysts were measured by nitrogen gas adsorption-desorption at liquid nitrogen temperature (-196°C) using a BET SORP mini II. The catalysts were pretreated in helium gas at 180°C for 3 hours.

4.3.3 H_2 chemisorption

The H_2 chemisorption technique was performed to measure the active site, dispersion and particle size of Ru metal, by using a Micrometitics AutoChem 2910 instrument. Prior to measurement, 60 mg of catalyst sample was reduced in H_2 gas (25 ml/min) at 400°C for 2 hours. Then, the reduced sample was cooled down to 100°C and measured at this temperature using N_2 carrier gas. 50 μl of H_2 gas was injected in the form of a pulse into instrument until amount of H_2 measured was constant.

4.3.4 Temperature programmed reduction (TPR)

The reduction behavior and reducibility of catalyst were obtained from Temperature programmed reduction (TPR) experiment using a Micrometritics AutoChem 2910 instrument. Prior to H_2 -TPR experiment, about 100 mg of catalyst sample was loaded into a U-shape quartz reactor and then, pretreated with N_2 gas (30 ml/min) at 200°C with heating rate of $10^\circ\text{C}/\text{min}$ for 1 hour to remove the adsorbed water. After pretreatment, the pretreated sample was cooled to room temperature. Then, 10% H_2 in N_2 (30 ml/min) was flowing through the sample and heated up to 800°C with rate of $10^\circ\text{C}/\text{min}$.

4.3.5 Transmission electron microscope (TEM)

The morphology of catalyst sample was determined by Phillips Tecni 20 and operated at 120 kV.

CHAPTER V

RESULTS AND DISCUSSION

In this chapter, the story is divided into four major sections, which consists: 1) effect of different ruthenium precursors in Ru/ γ -Al₂O₃ catalyst, 2) effect of ZrO₂ addition in γ -Al₂O₃ supported Ru catalyst, 3) effect of TiO₂ addition in γ -Al₂O₃ supported Ru catalyst and then 4) Comparison of catalytic activity of ZrO₂-Al₂O₃ and TiO₂-Al₂O₃ supported Ru catalysts. The first three major sections describe about characterization of catalyst which analyzed by five techniques, viz., N₂ physisorption (BET), transmission electron microscope (TEM), X-ray diffraction (XRD), H₂ chemisorption and temperature programmed reduction (TPR) techniques.

In addition, CO₂ hydrogenation reaction with temperature programmed is considered for catalytic activity investigation. Feed gases used in this reaction contain 12.5% CO₂ and 37.5% H₂ with He balanced for section one, and 12.5% CO₂ and 50% H₂ with He balanced for section two and three. GHSV specified is 14,416 h⁻¹.

5.1 Effect of different ruthenium precursors in Ru/ γ -Al₂O₃ catalyst

In this section, the Ru/ γ -Al₂O₃ catalysts prepared by incipient wetness impregnation method using three different ruthenium precursors are investigated. The three different ruthenium precursors included ruthenium (III) nitrosyl nitrate solution, ruthenium (III) acetylacetonate and hexaammineruthenium (III) chloride. The catalysts prepared by these precursors denoted as RNN, RAA and RCL, respectively. The amount of ruthenium loading is 1 wt.%.

5.1.1 Catalytic characterization

BET surface area, total pore volume and average pore size diameter of RNN, RAA and RCL catalysts are shown in **Table 8**. The BET surface area of RAA catalyst (192 m²/g) is higher than two other catalysts. When consider the different ruthenium precursor catalysts, the BET surface area of RNN (171 m²/g) and RCL catalysts (155 m²/g) are lower than that of RAA, respectively. In addition, the RAA catalyst is highest pore volume (0.91 cm³/g). The pore volume of both of the RNN and RCL catalysts are same value (0.21 cm³/g).

Table 8 BET surface area, pore volume, pore diameter, isotherm type and hysteresis loop type of Ru/ γ -Al₂O₃ catalysts prepared with three different ruthenium precursors.

Catalyst	BET surface area [m ² /g]	Pore volume [cm ³ /g]	Pore diameter [nm]	Type of isotherm	Type of hysteresis loop
RNN	171	0.21	5.0		
RAA	192	0.91	4.0	IV(a)	H2(b)
RCL	155	0.21	5.5		

Figure 10 Pore diameter distribution of RNN catalyst.

Figure 11 Pore diameter distribution of RAA catalyst.

Figure 12 Pore diameter distribution of RCL catalyst.

Pore diameter distribution of RNN, RAA and RCL catalysts analyzed by using BJH method are shown in **Figure 10 – 12**. All catalysts exhibited the very uniform narrow distribution curve. The pore diameter in descending sort is RCL (5.5 nm), RNN (5.0 nm) and RAA (4.0 nm), respectively. In addition, pore structure of all catalyst is mesopore that is confirmed in isotherm and hysteresis description.

The physisorption isotherms of RNN, RAA and RCL are exhibited in **Figure 13 – 15**, respectively. The physisorption isotherms of these catalysts are assigned as that in type IV(a). This type indicate that the catalysts have characteristic as mesoporous structure. In addition, the porous catalysts are cylindrical porous structure which described by hysteresis loop of type H2(b) [58]. The hysteresis loops are also shown in **Figure 13 – 15**.

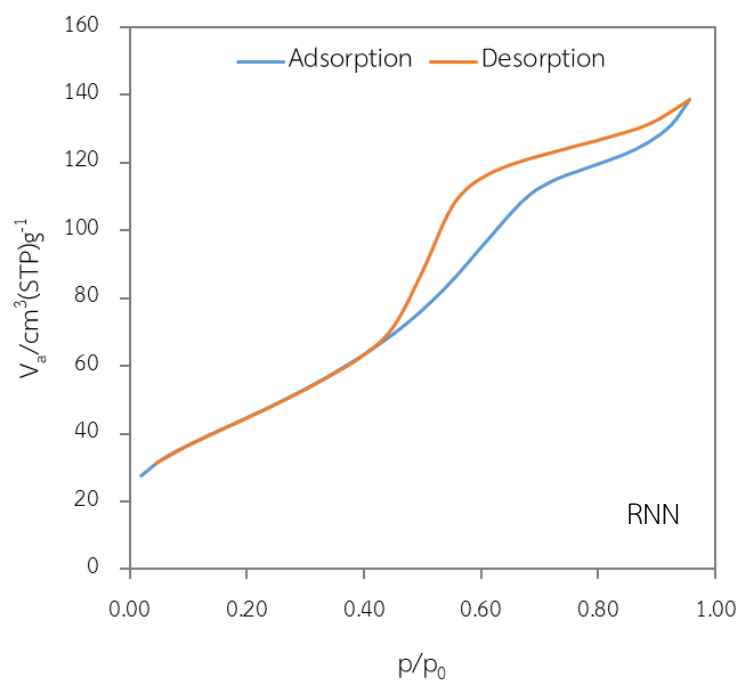

Figure 13 N_2 adsorption and desorption isotherm of RNN catalyst.

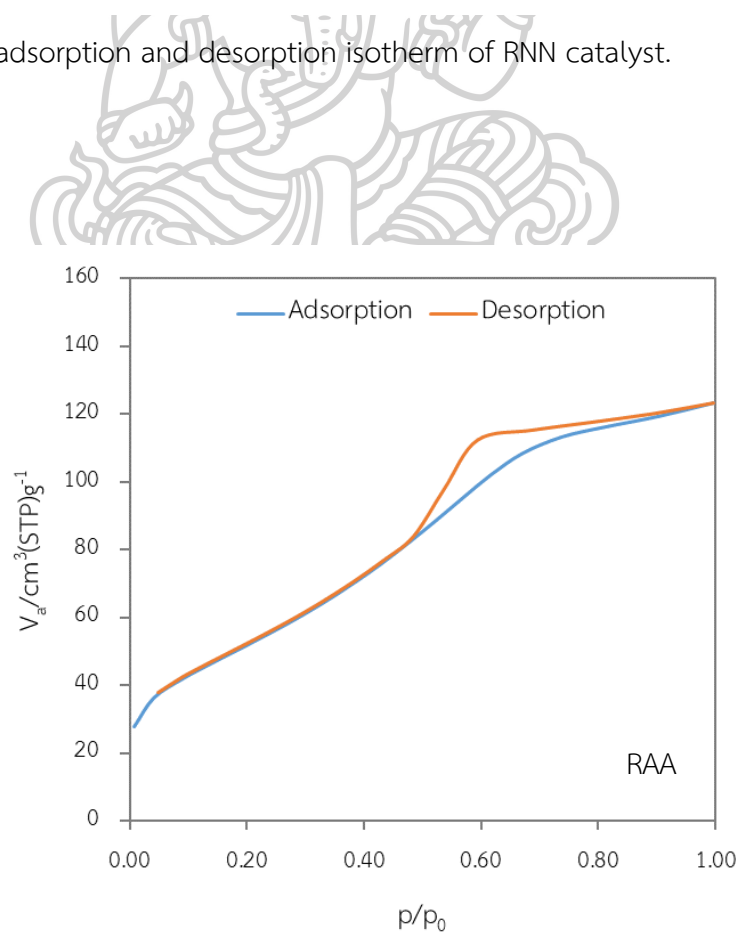

Figure 14 N_2 adsorption and desorption isotherm of RAA catalyst.

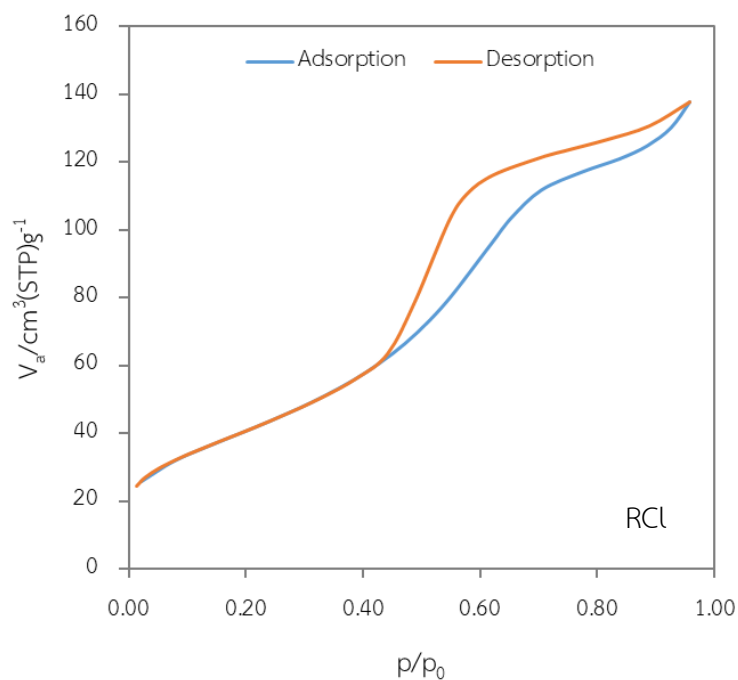

Figure 15 N_2 adsorption and desorption isotherm of RCL catalyst.

Figure 16 shows the XRD pattern of RNN, RAA and RCL catalysts. From all catalysts, the main diffraction peaks of RuO_2 is appeared at $2\theta = 28^\circ$, which is the same peak observed by Li D. et al. [4]. The RuO_2 peak intensity of RNN and RAA catalysts is much sharper comparing with RCL catalyst, which almost does not appear. In addition, the diffraction peak intensity of $\gamma-Al_2O_3$ are also observed in all $Ru/\gamma-Al_2O_3$ catalysts prepared by using various Ru precursors. The crystallite size of all species in RNN, RAA and RCL catalysts is calculated by using the Scherrer equation and the results are shown in **Table 9**. It clearly showed that RuO_2 crystallite size of RCL catalyst (24 nm) is smaller than the crystallite size of RNN and RAA catalysts (31 and 37 nm, respectively). These results are contributed with XRD results by Nurunnabi, M., et al. [59] which they investigate in effect of Ru precursors on Ru/Al_2O_3 catalyst. They found that RuO_2 crystallite size of Ru/Al_2O_3 prepared by $RuCl_3 \cdot nH_2O$ precursor was smaller than the catalyst prepared by $Ru(NO_3)_3(NO)$ and acetone solution of $Ru(C_5H_7O_2)_3$ precursors, respectively. In an observation of Al_2O_3 crystallite size, the size of all three catalysts are not much different.

Figure 16 XRD pattern of RNN, RAA and RCL catalysts.

Table 9 Crystallite size of RNN, RAA and RCL catalysts calculated by XRD results.

Catalyst	Crystallite size (nm)	
	RuO ₂	Al ₂ O ₃
RNN	31	6.3
RAA	37	5.9
RCL	24	6.4

Particle morphology of RNN, RAA and RCl catalysts observed by TEM technique are shown in **Figure 17**. In the TEM images, RuO₂ particles exhibited as deep black color. The RuO₂ particles of RNN catalyst were obviously larger than that of RCl catalyst and the RuO₂ particle shape of both catalysts cannot be identified in geometric form. In RAA catalyst, the RuO₂ was very large particle. Moreover, part of the RuO₂ particles in RAA catalyst were similar to crystalline rods. It is seemly that the above description has the same tendency as the XRD results. In addition, the RuO₂ particles of all three catalysts are quite poorly dispersed on γ -Al₂O₃ support and it is like to cluster form.

Amount of active site, Ru metal dispersion and Ru particle size of RNN, RAA and RCl catalysts are displayed in **Table 10**. The active site of RNN catalyst (3.0 $\mu\text{mol/g}_{\text{cat}}$) was higher than that of RAA catalyst (2.1 $\mu\text{mol/g}_{\text{cat}}$). In the Ru dispersion results, Ru dispersion of RNN catalyst as 3.0% was higher than Ru dispersion in RAA catalyst as 2.1%. This means that Ru metal from ruthenium (III) nitrosyl nitrate precursor dispersed on γ -Al₂O₃ support is better than Ru metal from ruthenium (III) acetylacetonate precursor. In addition, average Ru particle size of RNN catalyst is smaller than Ru particle size of RAA catalyst as 30 and 43 nm, respectively. Interestingly, results of active site, Ru metal dispersion and Ru particle size in RCl catalyst cannot be measured that probably due to existence of chlorine residual. Murata S. et al. [60] explained reason for low dispersion and low activity of Ru/Al₂O₃ catalyst prepared from RuCl₃·3H₂O precursor that because of chlorine residual. Moreover, when chlorine removed by hydrogen treatment at high temperature and washing in ammonia solution, the activity of this catalyst was increased about four times.

Figure 17 TEM images of Ru/ γ -Al₂O₃ catalysts seeing that (A) RNN catalyst, (B) RCL catalyst and (C), (D) RAA catalyst.

Table 10 H₂ chemisorption results of RNN, RAA and RCL catalysts.

Catalyst	Active site [$\mu\text{mol/g}_{\text{cat.}}$]	Ru dispersion [%]	Average diameter of Ru particles [nm]
RNN	3.0	3.0	30
RAA	2.1	2.1	43
RCL	N/A	N/A	N/A

**Figure 18** H₂-TPR profiles of RNN, RAA and RCL catalysts.

Figure 18 indicates H₂-TPR profiles of RNN, RAA and RCl catalysts. These results were composed of a sharp low temperature reduction peak at about 154 – 173°C, a medium temperature reduction peak at about 241 – 267°C, and a broad high temperature reduction peak at about 392 – 395°C. In literatures discovered [59, 61-63], the first peak and second peak were attributed to reduction step from RuO₂ to RuO and RuO to Ru⁰, respectively. Then, third peak at high reduction temperature can be assigned to reduction of Ru species oxidized that strongly interact with γ -Al₂O₃ support.

5.1.2 Catalytic activity test

CO₂ hydrogenation reaction is investigated with Ru/ γ -Al₂O₃ catalysts prepared by using three different Ru precursors. Feed gases mixed of H₂/CO₂ as 3/1 with He balanced and GHSV as 14,416 h⁻¹ are used in this investigation. Temperature programmed CO₂ conversion of RNN, RAA and RCl catalysts is indicated in **Figure 19**. CO₂ conversion profiles of RNN and RAA catalysts are little different while that of RCl catalyst was significantly lower than other two catalysts for all reaction temperatures. Reason of lower CO₂ conversion in RCl catalyst might be the presence of chlorine residual that caused the overlaid of active catalyst by chlorine [60]. In addition, Ru catalyst supported on commercial γ -Al₂O₃ was used to compare with RNN. Both catalysts were prepared by using same Ru precursor as ruthenium (III) nitrosyl nitrate precursor. The Ru/Al₂O₃ (Commercial) catalyst can get maximum CO₂ conversion at lower reaction temperature at 350°C than that of RNN catalyst. Besides, CO₂ conversion of Ru/Al₂O₃ (Commercial) catalyst decreased when increasing toward high reaction temperature probably due to the catalytic deactivation.

Plot between CH_4 selectivity and reaction temperature is shown in **Figure 20**. The CH_4 selectivity of RNN and RAA catalysts was almost 100%, whereas, the CH_4 selectivity of RCL is less than that of all catalysts at every reaction temperature. The result suggests that the RCL catalyst promotes production of CO. Plot between CH_4 yield and CO yield with reaction temperature are exhibited in **Figure 21 and 22**. The CH_4 yield profile of RCL catalyst was lower than that of RNN and RAA catalysts, and RCL catalyst gave the most CO yield of all catalysts. The CH_4 yield of $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalyst was higher than RNN catalyst at low reaction temperature, whereas, at high reaction temperature, the CH_4 yield of $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalyst decreased and the CO yield of $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalyst increased and then it was overtaking by RNN and RAA catalyst.

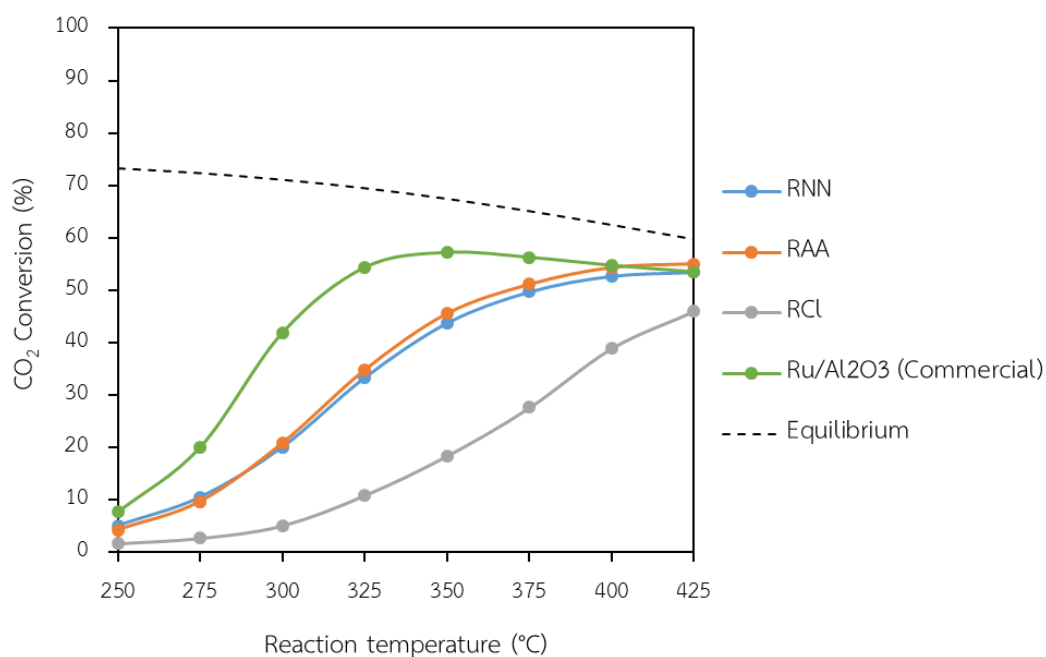

Figure 19 CO_2 conversion as function of reaction temperature of RNN, RAA, RCL and $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalysts.

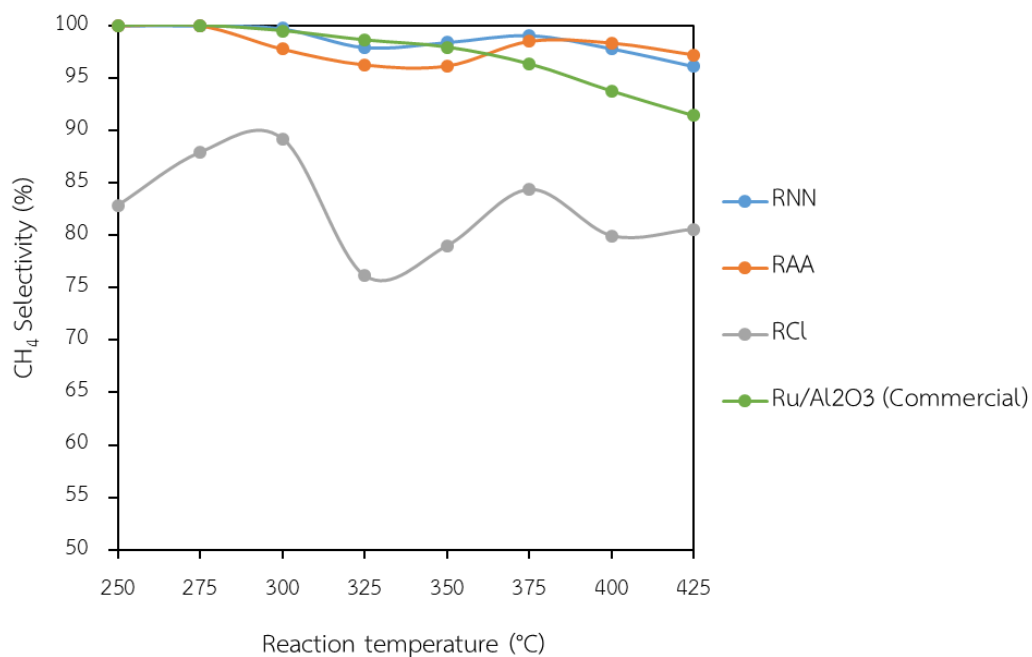

Figure 20 CH₄ selectivity as function of reaction temperature of RNN, RAA, RCL and Ru/Al₂O₃ (Commercial) catalysts.

Figure 21 CH₄ yield as function of reaction temperature of RNN, RAA, RCL and Ru/Al₂O₃ (Commercial) catalysts.

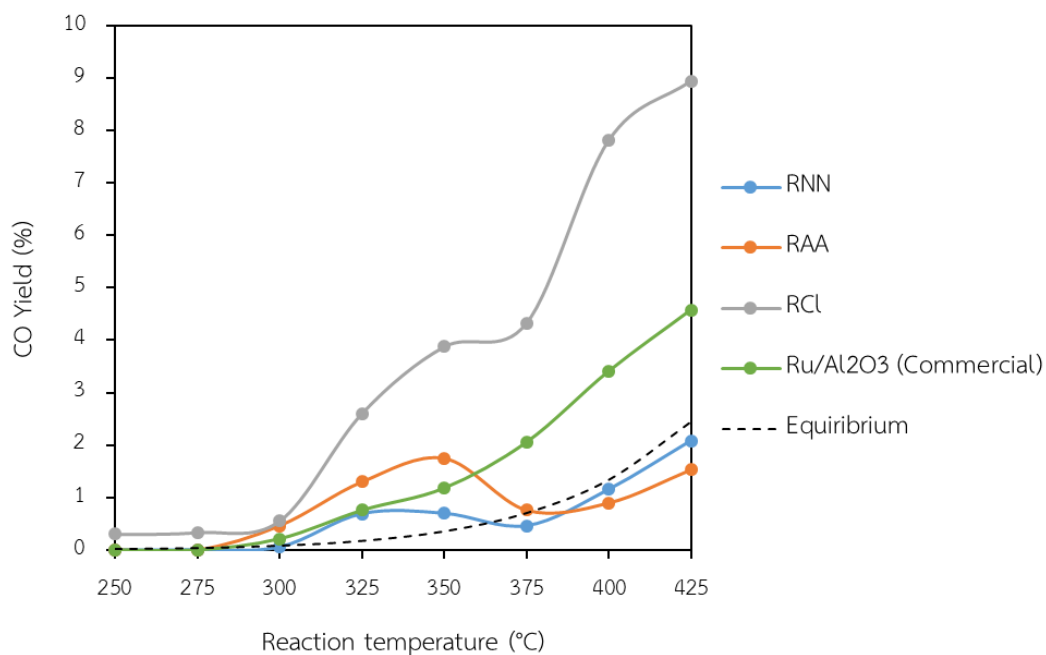

Figure 22 CO yield as function of reaction temperature of RNN, RAA, RCl and Ru/Al₂O₃ (Commercial) catalysts.

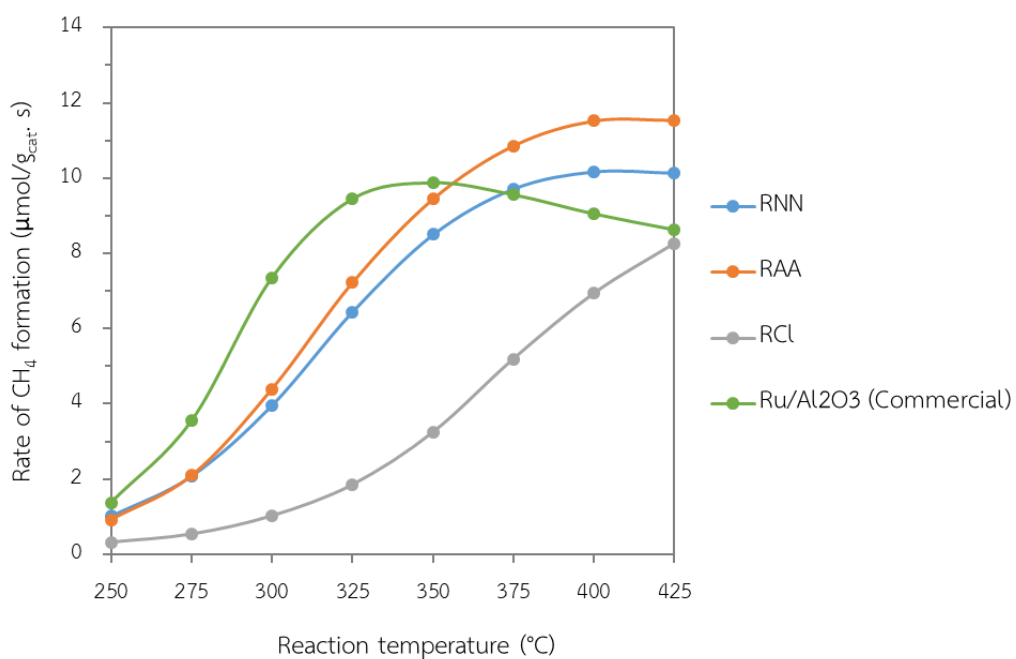

Figure 23 Rate of CH₄ formation as function of reaction temperature of RNN, RAA, RCl and Ru/Al₂O₃ (Commercial) catalysts.

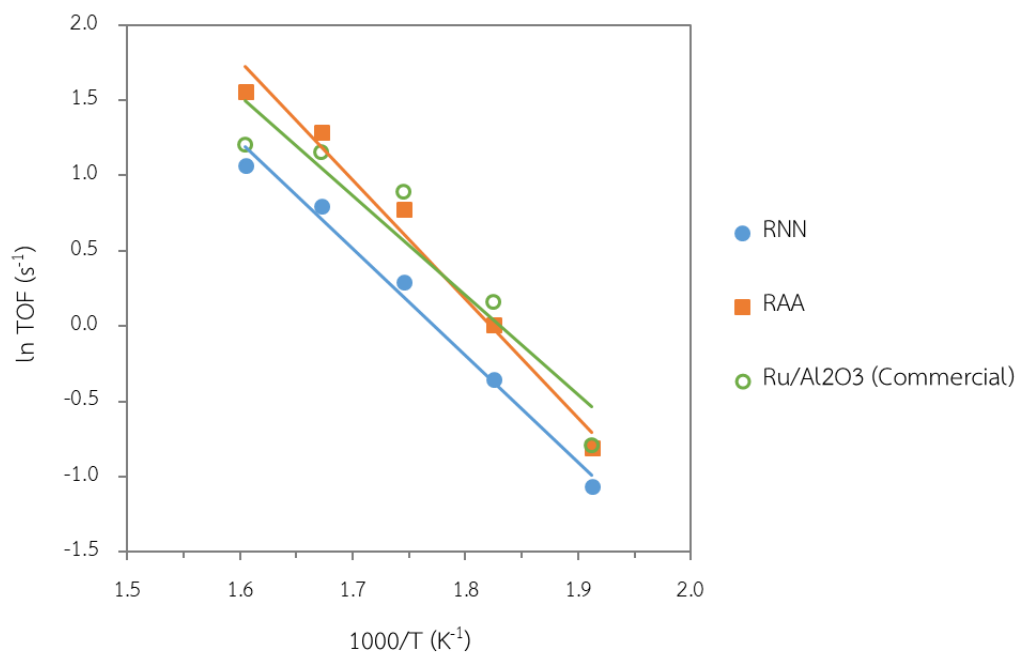

Figure 24 Turnover frequency (TOF) of CO₂ conversion obtained from RNN, RAA, RCL and Ru/Al₂O₃ (Commercial) catalysts.

Table 11 Apparent activation energy (E_a) of CO₂ hydrogenation reaction obtained from RNN, RAA, RCL and Ru/Al₂O₃ (Commercial) catalysts.

Catalyst	E_a [kJ/mol]
RNN	68
RAA	79
RCL	N/A
Ru/Al ₂ O ₃ (Commercial)	91

Figure 23 exhibits the plot between rate of CH₄ formation and reaction temperature of RNN, RAA and RCl catalysts comparing with Ru/Al₂O₃ (Commercial) catalyst. The CH₄ formation rate of RNN and RAA catalysts are significantly higher than RCl catalyst. These results mean that a gram of RNN and RAA catalysts can produce CH₄ more than RCl catalyst. In addition, turnover frequencies (TOF) of CO₂ conversion of RNN, RAA and RCl catalysts are shown in **Figure 24** which observed at reaction temperature between 250 to 350°C. The TOF of RCl catalyst could not report due to the active site of this catalyst could not measure. In an observation, the TOF of RNN catalyst was lower than that of RAA catalyst and also Ru/Al₂O₃ (Commercial).

The apparent activation energies (E_a) of CO₂ hydrogenation reaction over RNN, RAA, RCl and Ru/Al₂O₃ (Commercial) catalysts are shown in **Table 11**. These results were calculated from the slopes of linear lines in **Figure 24**. It is observed that these results are similar to E_a values of Ru/Al₂O₃ catalysts in CO₂ hydrogenation [51].

As the results description above, Ru/Al₂O₃ catalyst prepared by ruthenium (III) nitrosyl nitrate precursor or RNN catalyst can give high catalytic activity and high stability, and also solvent used in the preparation of this catalyst is more safety and environmental friendly than others. Therefore, ruthenium (III) nitrosyl nitrate precursor is used as Ru precursor for all catalysts in further two section.

5.2 Effect of ZrO₂ addition in γ -Al₂O₃ supported Ru catalyst

In this section, Ru catalysts supported on ZrO₂-Al₂O₃ prepared by using ruthenium (III) nitrosyl nitrate precursor are investigated with various ZrO₂ content as 5, 10, 15 and 20 wt.%. These Ru/ZrO₂-Al₂O₃ catalysts are compared with Ru/ γ -Al₂O₃ or RNN catalyst and Ru/ γ -Al₂O₃ or Ru/Al₂O₃ (Commercial) catalyst.

5.2.1 Catalytic characterization

BET surface area, pore volume and pore diameter of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts are shown in **Table 12**. BET surface area of catalysts decreased with ZrO₂ presence and these results were almost no different. Pore volume and pore diameter of Ru/5%ZrO₂-Al₂O₃ was larger than RNN catalyst, and then, that decreased with increasing amount of ZrO₂ in support. In addition, the BET surface area of Ru/Al₂O₃ (Commercial) catalyst (158 m²/g) was less than that of RNN catalyst (171 m²/g) while pore volume and pore diameter of Ru/Al₂O₃ (Commercial) catalyst as 0.23 cm³/g and 5.8 nm were higher than those of RNN catalyst as 0.21 cm³/g and 5.0 nm, respectively.

Table 12 BET surface area, pore volume, pore diameter, isotherm type and hysteresis loop type of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Catalyst	BET surface area [m ² /g]	Pore volume [cm ³ /g]	Pore diameter [nm]	Type of isotherm	Type of hysteresis loop
Ru/Al ₂ O ₃ (commercial)	158	0.23	5.8		
RNN	171	0.21	5.0		
Ru/5%ZrO ₂ -Al ₂ O ₃	142	0.22	6.1	IV(a)	H2(b)
Ru/10%ZrO ₂ -Al ₂ O ₃	136	0.19	5.5		
Ru/15%ZrO ₂ -Al ₂ O ₃	146	0.18	5.0		
Ru/20%ZrO ₂ -Al ₂ O ₃	149	0.18	4.9

Figure 29 Pore diameter distribution of Ru/15%ZrO₂-Al₂O₃ catalyst.

Figure 30 Pore diameter distribution of Ru/20%ZrO₂-Al₂O₃ catalyst.

Pore diameter distributions of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts analyzed by BJH method are shown in **Figure 25 – 30**. The RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts exhibited a narrow pore diameter distribution. Pore structure of these catalyst was same structure as mesopore. It is further described in N₂ adsorption and desorption isotherm and hysteresis loop.

N₂ adsorption and desorption isotherm of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts are exhibited in **Figure 31 – 36**. The physisorption isotherms of all catalysts were assigned to type IV(a). This type is described that the catalysts is mesopores structure. In addition, types of hysteresis loop of these all catalysts were H2(b). The type of H2(b) is specified that porous characteristics of catalysts are cylindrical porous structure [58].

Figure 37 indicates XRD patterns of RNN, Ru/ Al_2O_3 (Commercial) and Ru/ ZrO_2 - Al_2O_3 catalysts. This figure appeared peak of RuO_2 in all catalysts which the positions of this peak consisted to $2\theta = 28^\circ$, 35° and 54.5° [4]. The catalysts of ZrO_2 presence could be clearly seen that ZrO_2 formed in tetragonal structure and its main diffraction peak was specified as $2\theta = 30^\circ$ [64]. In observing, the intensity of ZrO_2 peak increased with increasing amount of ZrO_2 loading.

Figure 37 XRD pattern of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Table 13 Crystallite size of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts calculated by XRD results.

Catalyst	Crystallite size (nm)		
	RuO ₂	Al ₂ O ₃	ZrO ₂
Ru/Al ₂ O ₃ (Commercial)	31	5.6	-
RNN	31	6.3	-
Ru/5%ZrO ₂ -Al ₂ O ₃	14	6.3	5.2
Ru/10%ZrO ₂ -Al ₂ O ₃	27	6.0	11.8
Ru/15%ZrO ₂ -Al ₂ O ₃	31	6.3	12.9
Ru/20%ZrO ₂ -Al ₂ O ₃	37	6.1	12.2

Crystallite size of each species in RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts calculated by using the Scherrer's equation is indicated in **Table 13**. It was observed that crystallite sizes of RuO₂ in RNN and Ru/Al₂O₃ (Commercial) catalysts were the same size (31 nm) which it meant that the Al₂O₃ phase did not affect to crystallite size of metal oxide. Interesting, the crystallite size of RuO₂ decreased to 14 nm when ZrO₂ added small amount in support (Ru/5%ZrO₂-Al₂O₃). Whereas, the crystallite size of RuO₂ increased to 27 nm for Ru/10%ZrO₂-Al₂O₃ catalyst, and also increased to 37 nm when added ZrO₂ further to 20%ZrO₂. The crystallite size of Al₂O₃ seemed similarly in all catalysts as about 6 nm, while the ZrO₂ crystallite size of various Ru/ZrO₂-Al₂O₃ catalysts increased with increasing amount of ZrO₂ added.

Figure 38 TEM images of RNN catalyst (A) and Ru/Al₂O₃ (Commercial) catalyst (B).

Figure 39 TEM images of Ru/ZrO₂-Al₂O₃ catalysts seeing that (A) Ru/5%ZrO₂-Al₂O₃ catalyst, (B) Ru/10%ZrO₂-Al₂O₃ catalyst, (C) Ru/15%ZrO₂-Al₂O₃ catalyst and (D) Ru/20%ZrO₂-Al₂O₃ catalyst.

Figure 40 EDS spectra obtained at the area in cycle that presented in TEM image of Ru/20%ZrO₂-Al₂O₃ catalyst.

TEM images of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts are exhibited in **Figure 38 and 39**. The deep black parts were assigned as RuO₂. It appeared fine particles and smaller particles size of RuO₂ on γ -Al₂O₃ support than the particles size of RuO₂ in RNN catalyst. Whereas, some particles of RuO₂ in Ru/Al₂O₃ (Commercial) catalyst were large size and similar to RNN catalyst. These large RuO₂ particles of RNN and Ru/Al₂O₃ (Commercial) catalysts seemed as result of particle aggregation to cluster form. In an observation in Ru/ZrO₂-Al₂O₃ catalysts, the RuO₂ particles of Ru/5%ZrO₂ catalyst were smaller than other Ru/ZrO₂-Al₂O₃ catalysts, and highly dispersed on support. Moreover, the particles size of RuO₂ increased with increasing ZrO₂ composition in χ -Al₂O₃ support which these results were the same trend to their XRD results. An EDS spectrum of area in the cycle of Ru/20%ZrO₂-Al₂O₃ catalyst is presented in **Figure 40**. It could confirm the above description that the deep dark parts were assigned to RuO₂.

Active site, Ru metal dispersion and average Ru particle size of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts are represented in **Table 14**. The active site of RNN catalyst was same that of Ru/Al₂O₃ (Commercial) catalyst which it was 3.0 $\mu\text{mol/g}_{\text{cat}}$. Both Ru dispersion and average Ru particle size of RNN catalyst were almost same value as those of Ru/Al₂O₃ (Commercial) catalyst. In ZrO₂ adding in support observed that the catalysts with ZrO₂ presence gave more active site and Ru dispersion which Ru/10%ZrO₂-Al₂O₃ catalyst could indicate the highest active site and Ru dispersion as 9.7 $\mu\text{mol/g}_{\text{cat}}$ and 9.8%, respectively. But at large amount of ZrO₂ loading, the active site and Ru dispersion of Ru/15%ZrO₂-Al₂O₃ catalyst decreased and the Ru/20%ZrO₂-Al₂O₃ catalyst was the least active site and Ru dispersion. In the explanation above, ZrO₂ addition in γ -Al₂O₃ support of Ru catalyst could improve active site and metal dispersion. Whereas, the presence of high amount of ZrO₂ or more than 10%ZrO₂ affected to decreased active site and metal dispersion which it was probably due to RuO₂ aggregation.

Table 14 H₂ chemisorption results of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Catalyst	Active site [$\mu\text{mol/g}_{\text{cat}}$]	Ru dispersion [%]	Average diameter of Ru particles [nm]
Ru/Al ₂ O ₃ (commercial)	3.0	3.1	29
RNN	3.0	3.0	30
Ru/5%ZrO ₂ -Al ₂ O ₃	5.1	5.2	17
Ru/10%ZrO ₂ -Al ₂ O ₃	9.7	9.8	9
Ru/15%ZrO ₂ -Al ₂ O ₃	5.7	5.8	16
Ru/20%ZrO ₂ -Al ₂ O ₃	2.1	2.1	43

Figure 41 indicates H₂-TPR profiles of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts. The results were composed to two sharp low reduction temperature peaks and a broad high reduction temperature peaks. As according to several literatures [59, 61-63], the two peaks of low reduction temperature could be assigned to the reduction of RuO₂ to RuO and RuO to Ru⁰, respectively. A high reduction temperature peaks could be attributed to Ru oxidized reduction that strongly interaction with support. In an observation, the second and third reduction peaks of Ru catalysts with ZrO₂ presence were shifted to higher reduction temperature with increasing amount ZrO₂ loading. Moreover, these two reduction peaks of Ru/20%ZrO₂-Al₂O₃ catalyst were more shifted to higher reduction temperature than other Ru catalysts with ZrO₂ loading. In Ru/20%ZrO₂-Al₂O₃ catalyst, it appeared the fourth reduction peak at very high reduction temperature of about 625°C. This small broad peak was assigned to reduction of ZrO₂ crystallites which similar result was reported by Souza, M.M.V.M. et al. [65]. They reported that 20%ZrO₂/Al₂O₃ was also appeared a small peak at reduction temperature of 650°C, whereas lower amount of ZrO₂ did not have reduction peak appeared.

Figure 41 H₂-TPR profiles of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

5.2.2 Catalytic activity test

Ru catalysts supported on various amount of ZrO₂ in γ -Al₂O₃ prepared by using ruthenium (III) nitrosyl nitrate precursor are investigated in CO₂ hydrogenation reaction. The amount of ZrO₂ added in support is varied as 5, 10, 15 and 20 wt.% of ZrO₂. A reaction gases mixture of 12.5% CO₂, 50% H₂ (4H₂/1CO₂) with He balanced, and GHSV = 14,416 h⁻¹ are used in this investigation. The various Ru/ZrO₂-Al₂O₃ catalysts are compared with Ru/ γ -Al₂O₃ or RNN and Ru/ γ -Al₂O₃ or Ru/Al₂O₃ (Commercial) catalysts.

Conversion of CO₂ as function of temperature obtained over RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts is plotted in **Figure 42**. The CO₂ conversion curves increased with increasing reaction temperature and they were almost the same conversion at high temperature which these curves could be approached to

thermodynamic equilibrium. These results are accorded to reports of Cai M. et al. [27]. They were presented the result of Ru/Al₂O₃. In increasing reaction temperature, CO₂ conversion was reached to thermodynamic equilibrium. In addition, ZrO₂ loading in support of Ru catalysts resulted to the CO₂ conversion increased and Ru/20%ZrO₂ catalyst indicated high CO₂ conversion at lower temperature than other catalysts. In Ru/Al₂O₃ (commercial) catalyst, CO₂ conversion increased with increasing reaction temperature, and also decreased suddenly at reaction temperature of 400°C that was probably because of catalytic deactivation at high temperature or sintering.

Figure 42 CO₂ conversion as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Figure 43 CH₄ selectivity as function of reaction temperature of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Figure 44 CH₄ yield as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Figure 45 CO yield as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Figure 43 is indicated plots of CH₄ selectivity of RNN, Ru/Al₂O₃ (commercial) and Ru/ZrO₂-Al₂O₃ catalysts with reaction temperature. All catalysts indicated excellent selectivity of CH₄ and almost 100% at all reaction temperatures. CH₄ yield as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts is shown in **Figure 44**. The CH₄ yield profiles indicated that the CH₄ yield increased with increasing reaction temperature, and the maximum CH₄ yield could shift to lower reaction temperature with increasing amount of ZrO₂ loading. In CO yields represented in **Figure 45**, the CO yields increased with increasing reaction temperature and those of all catalysts were lower than 5% of CO yield.

Figure 46 Rate of CH₄ formation as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

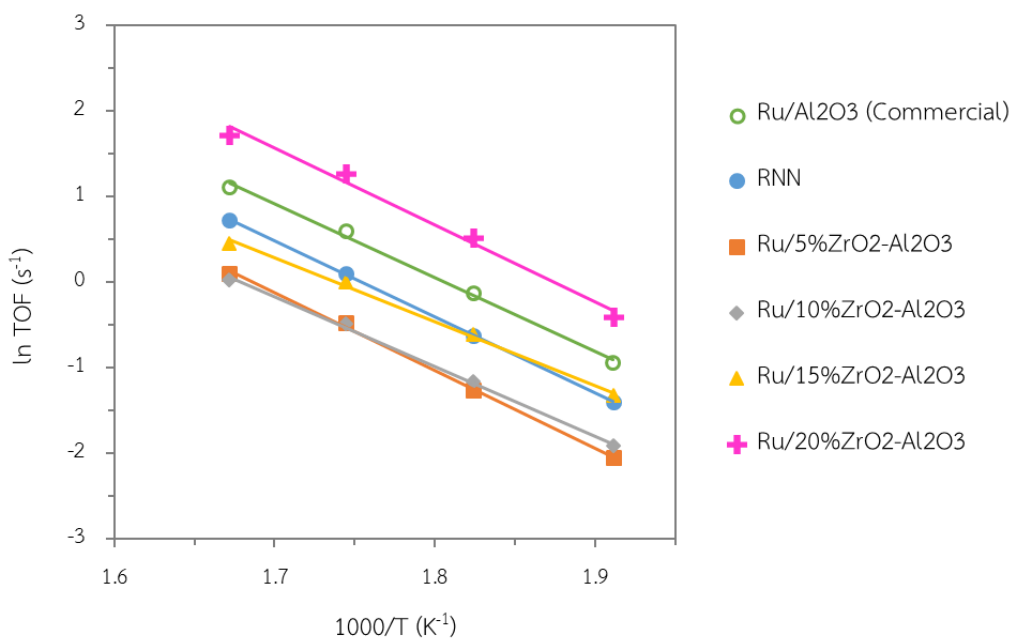

Figure 47 Turnover frequency (TOF) of CO₂ conversion obtained from RNN, Ru/Al₂O₃ (Commercial) and Ru/ZrO₂-Al₂O₃ catalysts.

Table 15 Apparent activation energy (E_a) of CO_2 hydrogenation reaction obtained from RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalysts.

Catalyst	E_a [kJ/mol]
$\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial)	78
RNN	75
$\text{Ru}/5\%\text{ZrO}_2\text{-Al}_2\text{O}_3$	79
$\text{Ru}/10\%\text{ZrO}_2\text{-Al}_2\text{O}_3$	71
$\text{Ru}/15\%\text{ZrO}_2\text{-Al}_2\text{O}_3$	67
$\text{Ru}/20\%\text{ZrO}_2\text{-Al}_2\text{O}_3$	88

Figure 46 indicates plots of CH_4 formation rate with reaction temperature obtained from RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalysts. The rate of CH_4 formation increased with increasing reaction temperature, and at the same time, with increasing amount of ZrO_2 added in support. The addition of ZrO_2 in catalyst, it encouraged the formation of CH_4 that was CO methanation promotion, resulting in CH_4 formation rate higher than the catalysts without ZrO_2 . Moreover, the $\text{Ru}/10\%\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalyst gave the maximum rate of CH_4 formation that was about $14.9 \mu\text{mol}/\text{g}_{\text{cat}} \cdot \text{s}$ at 400°C due to its maximum amount of active site.

Turnover frequencies (TOF) of CO_2 conversion obtained over RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalysts are summarized in **Figure 47**. It was observed that the activity per metal atom exposed decreased in order of $\text{Ru}/20\%\text{ZrO}_2\text{-Al}_2\text{O}_3 > \text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) $>$ RNN \sim $\text{Ru}/15\%\text{ZrO}_2\text{-Al}_2\text{O}_3 > \text{Ru}/10\%\text{ZrO}_2\text{-Al}_2\text{O}_3 \sim \text{Ru}/5\%\text{ZrO}_2\text{-Al}_2\text{O}_3$. In an interesting, the TOF line of $\text{Ru}/20\%\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalyst was higher than other all catalysts because it had stronger interaction between Ru and binary oxides support.

Apparent activation energies (E_a) of CO_2 hydrogenation reaction over RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalysts are indicated in **Table 15**. The E_a values of all catalysts were in range of E_a values of $\text{Ru}/\text{Al}_2\text{O}_3$ catalyst in CO_2 hydrogenation reaction [51].

5.3 Effect of TiO_2 addition in $\chi\text{-Al}_2\text{O}_3$ supported Ru catalyst

In this section, the effect of TiO_2 added in $\chi\text{-Al}_2\text{O}_3$ support of Ru catalysts is studied with $\text{Ru}/\chi\text{-Al}_2\text{O}_3$ or RNN catalyst and $\text{Ru}/\gamma\text{-Al}_2\text{O}_3$ or $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalyst comparison. All catalysts in this section are prepared by incipient wetness impregnation using ruthenium (III) nitrosyl nitrate precursor. The amount of TiO_2 added in support is varied as 2.5, 5, 10 and 15 wt.% TiO_2 .

5.3.1 Catalytic characterization

BET surface area, total pore volume and average pore size diameter of RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (commercial) and $\text{Ru}/\text{TiO}_2\text{-Al}_2\text{O}_3$ catalysts are exhibited in **Table 16**. In the increasing TiO_2 loading, the BET surface area decreased from $\text{Ru}/2.5\%\text{TiO}_2\text{-Al}_2\text{O}_3$ (178 m^2/g) to $\text{Ru}/15\%\text{TiO}_2\text{-Al}_2\text{O}_3$ (144 m^2/g), moreover, total pore volume and average pore size diameter increased to 0.25 cm^3/g and 7.0 nm of $\text{Ru}/15\%\text{TiO}_2\text{-Al}_2\text{O}_3$. In addition, Ru catalyst supported on $\chi\text{-Al}_2\text{O}_3$ or RNN catalyst had high BET surface area, low pore volume and small pore diameter than $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) catalyst.

Pore diameter distributions of RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (commercial) and $\text{Ru}/\text{TiO}_2\text{-Al}_2\text{O}_3$ catalysts are indicated in **Figure 48 and 53**. The pore diameter distributions of all catalysts appeared a narrow distribution. Mesoporous structure was assigned in pore structure of all catalysts which it was further explained in N_2 adsorption and desorption isotherm and hysteresis loop.

N_2 adsorption and desorption isotherm observed in catalysts of RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{TiO}_2\text{-Al}_2\text{O}_3$ are exhibited in **Figure 54 and 59**. The physisorption

isotherms type of all catalysts were specified to type IV(a). This isotherms type is assigned to mesopores structure of catalysts. In observation of hysteresis loop type, these all catalysts were H2(b) type. The hysteresis loop type of H2(b) is assigned that porous of catalysts are characterized as cylindrical porous structure [58].

Table 16 BET surface area, pore volume, pore diameter, isotherm type and hysteresis loop type of RNN, Ru/Al₂O₃ (commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Catalyst	BET surface area [m ² /g]	Pore volume [cm ³ /g]	Pore diameter [nm]	Type of isotherm	Type of hysteresis loop
Ru/Al ₂ O ₃ (commercial)	158	0.23	5.8		
RNN	171	0.21	5.0		
Ru/2.5%TiO ₂ -Al ₂ O ₃	178	0.21	4.7	IV(a)	H2(b)
Ru/5%TiO ₂ -Al ₂ O ₃	163	0.20	5.0

Catalyst	Crystallite size (nm)	% rutile-TiO ₂
----------	-----------------------	---------------------------

diffraction peaks of RuO₂ in all catalysts which the positions of diffraction peak of RuO₂ consisted to $2\theta = 28^\circ, 35^\circ$ and 54.5° [4]. In the catalysts with TiO₂ presence, diffraction peaks of TiO₂ appeared anatase phase in all these catalysts which the main diffraction peak of TiO₂-anatase phase is $2\theta = 25.3^\circ$. Moreover, diffraction peaks of TiO₂-rutile phase appeared only in Ru/10%TiO₂-Al₂O₃ and Ru/15%TiO₂-Al₂O₃ catalysts which the main diffraction peak is $2\theta = 27.4^\circ$ [66].

Table 17 Crystallite size of RNN, Ru/Al₂O₃ (commercial) and Ru/TiO₂-Al₂O₃ catalysts calculated by XRD results.

Figure 61 TEM images of (A) RNN and (B) Ru/Al₂O₃ (Commercial) catalysts.

Crystallite size of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts calculated by XRD results is reported in **Table 17**. The presence of TiO₂ in catalysts results in a smaller RuO₂ crystallite size. In addition, Crystallite size of both anatase and rutile phase of TiO₂ increase with increasing TiO₂ loading. Content of rutile phase in TiO₂ is calculated from equation presented by Yuangpho N. et al. [66] which Ru/10%TiO₂-Al₂O₃ and Ru/15%TiO₂-Al₂O₃ catalysts have 48% and 41% of rutile phase. Whereas, crystallite size of TiO₂-rutile phase in the catalysts added small amount of TiO₂ cannot be calculated because their diffraction peaks are not appearing or too weak for calculation. From the results above, anatase phase of TiO₂ can transform to rutile phase with increasing TiO₂ loading.

Figure 61 and 62 show TEM images of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts. Parts of deep black were assigned to RuO₂. In TEM images observed, RuO₂ particles was smaller with adding of TiO₂ in support and its particles size decreased with increasing amount of TiO₂ loading. Moreover, the RuO₂ particles of the catalyst with TiO₂ presence were seemed better dispersion than RNN catalyst. These results were similar to the results of crystallite size that was the RuO₂ crystallite size decreased with increasing TiO₂ loading. In Ru/2.5%TiO₂-Al₂O₃ catalyst, area cycled in TEM image was performed by EDS analysis that shown in **Figure 63**. The deep dark part in cycle was confirmed that Ru metal was primarily composed.

Figure 62 TEM images of Ru/TiO₂-Al₂O₃ catalysts seeing that (A) Ru/2.5%TiO₂-Al₂O₃ catalyst, (B) Ru/5%TiO₂-Al₂O₃ catalyst, (C) Ru/10%TiO₂-Al₂O₃ catalyst and (D) Ru/15%TiO₂-Al₂O₃ catalyst.

Table 18 H₂ chemisorption results of RNN, Ru/Al₂O₃ (commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Catalyst	Active site [$\mu\text{mol/g}_{\text{cat.}}$]	Ru dispersion [%]	Average diameter of Ru particles [nm]
Ru/Al ₂ O ₃ (commercial)	3.0	3.1	29
RNN	3.0	3.0	30
Ru/2.5%TiO ₂ -Al ₂ O ₃	3.5	3.5	26
Ru/5%TiO ₂ -Al ₂ O ₃	4.7	4.7	19
Ru/10%TiO ₂ -Al ₂ O ₃	3.6	3.7	24
Ru/15%TiO ₂ -Al ₂ O ₃	3.7	3.7	24

Active site, Ru dispersion and average Ru particles diameter of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts are shown in **Table 18**. In TiO₂ addition, their active site and Ru dispersion could increase. The maximum active site and also Ru dispersion were obtained by Ru/5%TiO₂-Al₂O₃ catalyst (4.7 μmol/g_{cat} and 4.7%, respectively). Moreover, average Ru particles diameter of the Ru/5%TiO₂-Al₂O₃ catalyst was smallest of all catalysts with TiO₂ added and also smaller than RNN and Ru/Al₂O₃ (Commercial) catalysts. In an interesting, the amount of TiO₂ loading further increased was shown decreasing of active site and Ru dispersion.

Figure 64 H₂-TPR profiles of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

H₂-TPR profiles of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts are shown in **Figure 64**. It was clear that consisted a low temperature reduction peak, a medium temperature reduction peak and a broad high temperature reduction peak. Accordance with the results reported in literatures [59, 61-63], the first reduction peak at low reduction temperature attributed to the reduction steps from RuO₂ to RuO and RuO to Ru⁰ at medium reduction temperature or second reduction peak. The broad reduction peak at high temperature might be assigned to the oxidized Ru species reduction that interaction strongly with support. In an observation, the second and third reduction peaks were shifted toward higher reduction temperature when TiO₂ added into the support. Moreover, Ru/15%TiO₂-Al₂O₃ catalyst indicated that two peaks at high reduction temperature were more shifted to high reduction temperature than other Ru catalysts with TiO₂ loading due to Ru was more interacted the binary oxides support.

5.3.2 Catalytic activity test

Ru catalysts supported on various amount of TiO₂ in γ -Al₂O₃ are investigated in CO₂ hydrogenation reaction. Feed gases mixed are consisted 12.5% CO₂, 50% H₂ (4H₂/1CO₂) with He balancing. GHSV of 14,416 h⁻¹ is used in this investigation. The results of Ru/TiO₂-Al₂O₃ catalysts are compared to Ru/ γ -Al₂O₃ (or RNN) and Ru/ γ -Al₂O₃ (or Ru/Al₂O₃ (Commercial)) catalysts.

CO₂ conversion as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts is illustrated in **Figure 65**. In TiO₂ added in support, its CO₂ conversion was higher than RNN catalyst and also increased with increasing TiO₂ loading. In an interesting, the maximum CO₂ conversion of large amount of TiO₂ loading could shift to lower reaction temperature. Moreover, Ru/5%TiO₂-Al₂O₃ catalyst gave the maximum CO₂ conversion and it could approach equilibrium more than other all catalysts.

Figure 65 CO₂ conversion as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Figure 66 CH₄ selectivity as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Figure 67 CH₄ yield as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Figure 68 CO yield as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

CH₄ selectivity of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts, and reaction temperature are plotted in **Figure 66**. The CH₄ selectivity of all catalysts could almost reach to 100% at every reaction temperature. **Figure 67 and 68** exhibit plots between CH₄ yield and CO yield with reaction temperature. The CH₄ yield of all catalysts increased rapidly with increasing reaction temperature and slowed down when approaching the equilibrium. The CH₄ yield curve of TiO₂-promoted catalyst shifted toward lower reaction temperature than RNN catalyst. Moreover, the CH₄ yield decreased in order of Ru/5%TiO₂-Al₂O₃ > Ru/15%TiO₂-Al₂O₃ > Ru/10%TiO₂-Al₂O₃ > Ru/Al₂O₃ (Commercial) > Ru/2.5%TiO₂-Al₂O₃ > RNN catalysts which obtained at reaction temperature of 350°C. The maximum CH₄ yield of Ru/5%TiO₂-Al₂O₃ catalyst was about 76% at 375°C, and then, it decreased with further increasing of reaction temperature. This probably due to the deactivation of catalyst. In addition, CO yield of all catalysts increased with increasing reaction temperature and did not more than 5% of CO yield. In an interesting, the addition of TiO₂ in support could reduce the amount of CO yield.

Plots between rate of CH₄ formation of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts, and reaction temperature are exhibited in **Figure 69**. In an observation, the amount of CH₄ formation per gram catalyst with TiO₂ presence was more than Ru catalyst without TiO₂ added. These results of CH₄ formation rate could confirm the description above that the addition of TiO₂ in support promoted CH₄ formation. In Ru/5%TiO₂-Al₂O₃ catalyst, it could get the maximum rate of CH₄ formation due to the amount of its active site was more than all catalysts that could be seen in H₂ chemisorption result.

Turnover frequencies (TOF) of CO₂ conversion are displayed in **Figure 70** which showing linearity in reaction temperature of 250 – 325°C. In an observation, the TOF of Ru/15%TiO₂-Al₂O₃ catalyst was obviously higher other all catalysts probably due to it had stronger interaction between Ru and binary oxides support. Decreasing order of TOF was followed as Ru/15%TiO₂-Al₂O₃ > Ru/10%TiO₂-Al₂O₃ ~ Ru/5%TiO₂-Al₂O₃ > Ru/Al₂O₃ (Commercial) > Ru/2.5%TiO₂-Al₂O₃ > RNN catalysts.

Figure 69 Rate of CH₄ formation as function of reaction temperature of RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Figure 70 Turnover frequency (TOF) of CO₂ conversion obtained from RNN, Ru/Al₂O₃ (Commercial) and Ru/TiO₂-Al₂O₃ catalysts.

Table 19 Apparent activation energy (E_a) of CO_2 hydrogenation reaction obtained from RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{TiO}_2\text{-Al}_2\text{O}_3$ catalysts.

Catalyst	E_a [kJ/mol]
$\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial)	78
RNN	75
$\text{Ru}/2.5\%\text{TiO}_2\text{-Al}_2\text{O}_3$	70
$\text{Ru}/5\%\text{TiO}_2\text{-Al}_2\text{O}_3$	74
$\text{Ru}/10\%\text{TiO}_2\text{-Al}_2\text{O}_3$	66
$\text{Ru}/15\%\text{TiO}_2\text{-Al}_2\text{O}_3$	94

Apparent activation energies (E_a) of RNN, $\text{Ru}/\text{Al}_2\text{O}_3$ (Commercial) and $\text{Ru}/\text{TiO}_2\text{-Al}_2\text{O}_3$ catalysts in CO_2 hydrogenation reaction are shown in **Table 19**. It could be calculated from slopes of fitted linear curves [67]. The E_a values of all catalysts were similar to results of $\text{Ru}/\text{Al}_2\text{O}_3$ catalyst in CO_2 hydrogenation reaction [51].

5.4 Comparison of catalytic activity of $\text{ZrO}_2\text{-Al}_2\text{O}_3$ and $\text{TiO}_2\text{-Al}_2\text{O}_3$ supported Ru catalysts.

In this section, $\text{Ru}/10\%\text{ZrO}_2\text{-Al}_2\text{O}_3$ and $\text{Ru}/20\%\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalysts are compared with $\text{Ru}/5\%\text{TiO}_2\text{-Al}_2\text{O}_3$ and $\text{Ru}/15\%\text{TiO}_2\text{-Al}_2\text{O}_3$ catalysts and also RNN catalyst. This comparison is determined in rate of CH_4 formation and turnover frequency (TOF) of those catalysts. Feed gases composition used is 12.5% CO_2 , 50% H_2 ($4\text{H}_2/1\text{CO}_2$) with He balancing. GHSV of $14,416 \text{ h}^{-1}$ is used in this investigation.

Figure 71 Rate of CH₄ formation as function of reaction temperature of Ru/10%ZrO₂-Al₂O₃, Ru/20%ZrO₂-Al₂O₃, Ru/5%TiO₂-Al₂O₃, Ru/15%TiO₂-Al₂O₃ and RNN catalysts.

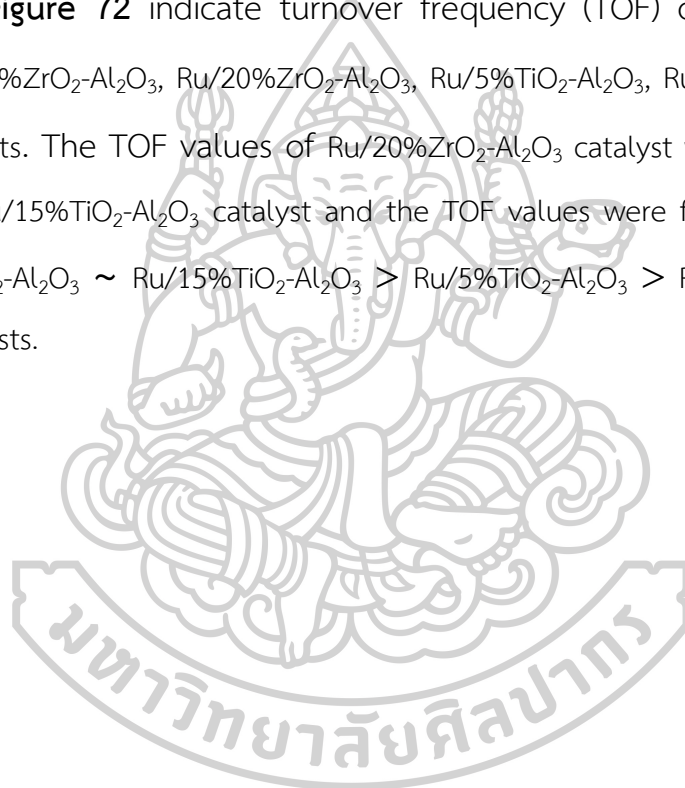

Figure 72 Turnover frequency (TOF) of CO₂ conversion obtained from Ru/10%ZrO₂-Al₂O₃, Ru/20%ZrO₂-Al₂O₃, Ru/5%TiO₂-Al₂O₃, Ru/15%TiO₂-Al₂O₃ and RNN catalysts.

Plot of CH₄ formation rate versus reaction temperature of Ru/10%ZrO₂-Al₂O₃, Ru/20%ZrO₂-Al₂O₃, Ru/5%TiO₂-Al₂O₃, Ru/15%TiO₂-Al₂O₃ and RNN catalysts is indicated in **Figure 71**. It observed that both ZrO₂ loading and TiO₂ loading in Ru catalysts were higher rate of CH₄ formation than RNN catalyst. Moreover, Ru catalysts with TiO₂ presence could give CH₄ formation rate more than Ru catalyst with ZrO₂ presence.

In **Figure 72** indicate turnover frequency (TOF) of CO₂ conversion over Ru/10%ZrO₂-Al₂O₃, Ru/20%ZrO₂-Al₂O₃, Ru/5%TiO₂-Al₂O₃, Ru/15%TiO₂-Al₂O₃ and RNN catalysts. The TOF values of Ru/20%ZrO₂-Al₂O₃ catalyst were not much with those of Ru/15%TiO₂-Al₂O₃ catalyst and the TOF values were followed in order of Ru/20%ZrO₂-Al₂O₃ ~ Ru/15%TiO₂-Al₂O₃ > Ru/5%TiO₂-Al₂O₃ > RNN > Ru/10%ZrO₂-Al₂O₃ catalysts.

CHAPTER VI

CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusion

6.1.1 Effect of ruthenium precursors

In this study, 1 wt.% Ru catalyst supported on γ -Al₂O₃ was prepared by incipient wetness impregnation method. Effect of three different ruthenium precursors including ruthenium (III) nitrosyl nitrate solution, ruthenium (III) acetylacetonate and Hexaammineruthenium (III) chloride used in catalytic preparation was investigated, which denoted as RNN, RAA and RCl catalysts. The RNN and RAA catalysts gave high active site and Ru dispersion, whereas, the active site of RCl catalyst could not determine. CO₂ conversion and selectivity of RNN and RAA catalysts were almost similar and higher than that of RCl catalyst, moreover, CH₄ yield of RNN and RAA catalysts were 2 times higher than RCl catalyst at reaction temperature of 400°C. The worst results of RCl was probably due to residual chlorine covered on the catalyst surface, which inhibited the adsorption of CO₂ and H₂ molecules.

6.1.2 Effect of ZrO₂ addition in γ -Al₂O₃ supported Ru catalyst

ZrO₂-Al₂O₃ with different Zr loading content varied as 5, 10, 15 and 20 wt.% was used as the support for Ru catalyst. The addition of ZrO₂ could improve active site and Ru dispersion of Ru/ γ -Al₂O₃ catalyst, moreover, Ru/10%ZrO₂-Al₂O₃ catalyst gave the highest active site and Ru dispersion (9.7 μ mol/g_{cat.} and 9.8%, respectively). In addition, Ru catalysts added with ZrO₂ could affect the interaction between Ru and binary oxides support. The Ru/ZrO₂-Al₂O₃ promoted CO₂ conversion and CH₄ yield. In addition of large amount of ZrO₂ to Ru catalysts (Ru/20%ZrO₂-Al₂O₃ catalyst),

it gave values of TOF more than Ru catalysts with other support due to the interaction between Ru and binary oxides support was stronger than other catalysts.

6.1.3 Effect of TiO₂ addition in χ -Al₂O₃ supported Ru catalyst

Ru catalyst supported on TiO₂-Al₂O₃ with different Ti loading content varied as 2.5, 5, 10 and 15 wt.% was investigated in this part. The Ru/TiO₂-Al₂O₃ exhibited higher active site, Ru dispersion and smaller RuO₂ particles size, and at the same time, the addition of TiO₂ in the Ru catalysts could improve interaction between Ru and binary oxides support. Moreover, the Ru catalysts with TiO₂ presence could give higher CH₄ formation rate than Ru catalyst without TiO₂ loading. The TOF values of large amount of TiO₂ loaded in Ru catalyst (Ru/15%TiO₂-Al₂O₃ catalyst) were higher than Ru catalysts with other support because Ru was stronger interact to binary oxides support than other Ru catalysts.

6.1.4 Comparison of catalytic activity of ZrO₂-Al₂O₃ and TiO₂-Al₂O₃ supported Ru catalysts.

Ru catalysts supported on 10%ZrO₂-Al₂O₃ and 20%ZrO₂-Al₂O₃ were compared with Ru catalysts supported on 5%TiO₂-Al₂O₃, 15%ZrO₂-Al₂O₃ and also Ru/ χ -Al₂O₃ catalyst. The addition of Ti and Zr in Ru catalysts could give better rate of CH₄ formation than Ru/ χ -Al₂O₃ catalyst. Moreover, Ru/TiO₂-Al₂O₃ catalysts could show higher CH₄ formation rate than Ru/ZrO₂-Al₂O₃ catalysts.

APPENDIX A

CALCULATION OF CATALYTIC PREPARATION

A.1 Calculation of support preparation

A.1.1 Calculation of ZrO_2/Al_2O_3 support preparation

Example: Preparation of 15% ZrO_2 supported on Al_2O_3 by wet impregnation.

In this preparation, properties information used for calculation is followed below.

- Formula of zirconium n-butoxide (ZNB) = $C_{16}H_{36}O_4Zr$
- Purity of zirconium n-butoxide solution = 80% w/w
- Density of zirconium n-butoxide solution (ρ_{ZNB}) = 1.07 g/ml
- Molecular weight of zirconium n-butoxide (MW_{ZNB}) = 383.68 g/mol
- Molecular weight of zirconium dioxide (MW_{ZrO_2}) = 123.22 g/mol
- Molecular weight of gibbsite (MW_{GB}) = 155.96 g/mol
- Molecular weight of aluminum oxide ($MW_{Al_2O_3}$) = 101.96 g/mol

Basis: Total weight of ZrO_2/Al_2O_3 = 2 g

Volume of zirconium n-butoxide solution (V_{ZNB}) is calculated by

$$m_{ZrO_2} = (2 \text{ g } ZrO_2/Al_2O_3) \times \frac{(15 \text{ g } ZrO_2)}{(100 \text{ g } ZrO_2/Al_2O_3)} = 0.30 \text{ g}$$

$$m_{ZNB \text{ sol.}} = 0.30 \text{ g } ZrO_2 \left| \frac{383.68 \text{ g/mol ZNB}}{123.22 \text{ g/mol } ZrO_2} \right| \frac{1 \text{ mol ZNB}}{1 \text{ mol } ZrO_2} \left| \frac{1 \text{ g ZNB sol.}}{0.8 \text{ g ZNB}} \right|$$

$$\therefore m_{ZNB \text{ sol.}} = 1.17 \text{ g}$$

$$V_{\text{ZNB sol.}} = \frac{m_{\text{ZNB sol.}}}{\rho_{\text{ZNB}}} = \frac{1.17 \text{ g}}{1.07 \text{ g/ml}} = 1.09 \text{ ml}$$

Weight of gibbsite is calculated by

$$m_{\text{Al}_2\text{O}_3} = (2 \text{ g ZrO}_2/\text{Al}_2\text{O}_3) \times \frac{(75 \text{ g Al}_2\text{O}_3)}{(100 \text{ g ZrO}_2/\text{Al}_2\text{O}_3)} = 1.70 \text{ g}$$

$$m_{\text{GB}} = 1.7 \text{ g Al}_2\text{O}_3 \left| \frac{155.96 \text{ g/mol GB}}{101.96 \text{ g/mol Al}_2\text{O}_3} \right| \frac{1 \text{ mol GB}}{1 \text{ mol Al}_2\text{O}_3}$$

$$\therefore m_{\text{GB}} = 2.60 \text{ g GB}$$

A.1.2 Calculation of TiO₂/Al₂O₃ support preparation

Example: Preparation of 15% TiO₂ supported on Al₂O₃ by wet impregnation.

In this preparation, properties information used for calculation is followed below.

- Formula of titanium (IV) butoxide (TNB) = Ti(OCH₂CH₂CH₂CH₃)₄
- Purity of titanium (IV) butoxide solution = 97% w/w
- Density of titanium (IV) butoxide solution = 1.00 g/ml
- Molecular weight of titanium (IV) butoxide (MW_{TNB}) = 340.32 g/mol
- Molecular weight of titanium dioxide (MW_{TiO₂}) = 79.87 g/mol
- Molecular weight of gibbsite (MW_{GB}) = 155.96 g/mol
- Molecular weight of aluminum oxide (MW_{Al₂O₃}) = 101.96 g/mol

Basis: Total weight of $\text{TiO}_2/\text{Al}_2\text{O}_3 = 2 \text{ g}$

Volume of titanium (IV) butoxide solution (V_{TNB}) is calculated by

$$m_{\text{TiO}_2} = (2 \text{ g TiO}_2/\text{Al}_2\text{O}_3) \times \frac{(15 \text{ g TiO}_2)}{(100 \text{ g TiO}_2/\text{Al}_2\text{O}_3)} = 0.30 \text{ g}$$

$$m_{\text{TNB sol.}} = 0.30 \text{ g TiO}_2 \left| \frac{340.32 \text{ g/mol TNB}}{79.87 \text{ g/mol TiO}_2} \right| \frac{1 \text{ mol TNB}}{1 \text{ mol TiO}_2} \left| \frac{1 \text{ g TNB sol.}}{0.97 \text{ g TNB}} \right|$$

$$\therefore m_{\text{TNB sol.}} = 1.32 \text{ g}$$

$$V_{\text{TNB sol.}} = \frac{m_{\text{TNB sol.}}}{\rho_{\text{TNB}}} = \frac{1.32 \text{ g}}{1.00 \text{ g/ml}} = 1.32 \text{ ml}$$

Weight of gibbsite is calculated by

$$m_{\text{Al}_2\text{O}_3} = (2 \text{ g ZrO}_2/\text{Al}_2\text{O}_3) \times \frac{(75 \text{ g Al}_2\text{O}_3)}{(100 \text{ g ZrO}_2/\text{Al}_2\text{O}_3)} = 1.70 \text{ g}$$

$$m_{\text{GB}} = 1.7 \text{ g Al}_2\text{O}_3 \left| \frac{155.96 \text{ g/mol GB}}{101.96 \text{ g/mol Al}_2\text{O}_3} \right| \frac{1 \text{ mol GB}}{1 \text{ mol Al}_2\text{O}_3}$$

$$\therefore m_{\text{GB}} = 2.60 \text{ g GB}$$

A.2 Calculation of catalytic preparation

Example: Preparation of 1% Ru supported on $\chi\text{-Al}_2\text{O}_3$ by incipient wetness impregnation with Ruthenium (III) nitrosyl nitrate precursor.

In this preparation, properties information used for calculation is followed below.

- Formula of ruthenium (III) nitrosyl nitrate (RNN) = $\text{Ru}(\text{NO})(\text{NO}_3)_x(\text{OH})_y$, $x + y = 3$
- Purity of ruthenium (III) nitrosyl nitrate solution = 1.5% (typical)
- Density of ruthenium (III) nitrosyl nitrate solution (ρ_{RNN}) = 1.07 g/ml

Basis: Total weight of support = 2 g

Volume of ruthenium (III) nitrosyl nitrate solution (V_{RNN}) is calculated by

$$m_{\text{RNN sol.}} = 2 \text{ g Al}_2\text{O}_3 \left| \frac{0.01 \text{ g Ru}}{0.99 \text{ g Al}_2\text{O}_3} \right| \frac{98.5 \text{ g RNN sol.}}{1.5 \text{ g Ru}}$$

$$\therefore m_{\text{RNN sol.}} = 1.33 \text{ g}$$

$$V_{\text{RNN sol.}} = \frac{m_{\text{RNN sol.}}}{\rho_{\text{RNN}}} = \frac{1.33 \text{ g}}{1.07 \text{ g/ml}} = 1.24 \text{ ml}$$

APPENDIX B

CALCULATION OF CRYSTALLITE SIZE

The Scherrer's equation is used to estimate the average crystallite size that shown in Eq. (B.1).

Figure 73 Observing the crystal plane of diffraction phenomenon [68].

The Scherrer's equation:

$$D = \frac{k\lambda}{\beta \cos\theta} \quad (B.1)$$

Where D is crystallite size, \AA .

K is constant dependent on crystallite shape = 0.9.

λ is x-ray wavelength = 1.54 \AA (for $\text{CuK}\alpha$).

β is the full width at half maximum which can be calculated by Warren's formula.

θ is Bragg angle.

The Warren's formula is used for β calculation that showed in Eq. (B.2).

$$\beta^2 = \beta_M^2 - \beta_S^2 \quad (\text{B.2})$$

Where β_M and β_S are the full width at half maximum in radians for the sample and standard, respectively. The β_S can be get from **Figure B.2**. This graph is the full width at half maximum in radians for $\alpha\text{-Al}_2\text{O}_3$ that used as standard

Figure 74 Graph of the full width at half maximum in radians for $\alpha\text{-Al}_2\text{O}_3$ that used as standard.

APPENDIX C
CALCULATION OF ACTIVE SITE, METAL DISPERSION
AND METAL PARTICLE SIZE

C.1 Calculation of active site

Active site of catalyst can be calculated by Eq. (C.1).

$$\text{Active site} = \frac{\text{Moles of metal chemisorbed } H_2}{\text{Total weight of catalyst}} = \frac{V_{H_2, STP} \times S}{W \times 22414} \quad (C.1)$$

Where $V_{H_2, STP}$ is volume of H_2 chemisorbed at STP, cm^3 .

W is total weight of catalyst, g.

S is stoichiometric factor of H_2 to Ru atom or $H_2/Ru = 2$

C.2 Calculation of metal dispersion

Metal dispersion can be calculated by Eq. (C.2) [69, 70].

$$\begin{aligned} \text{Metal dispersion (\%)} &= \frac{\text{Number of metal atoms chemisorbed } H_2}{\text{Total number of metal atoms in catalyst}} \\ &= \frac{V_{H_2, STP} \times S \times M \times 100}{\text{Metal weight \%}} \end{aligned} \quad (C.2)$$

Where $V_{H_2, STP}$ is volume of H_2 chemisorbed at STP, cm^3 .

M is molecular weight of metal, g/mol.

S is stoichiometric factor of H_2 to Ru atom or $H_2/Ru = 2$

C.3 Calculation of metal particle size

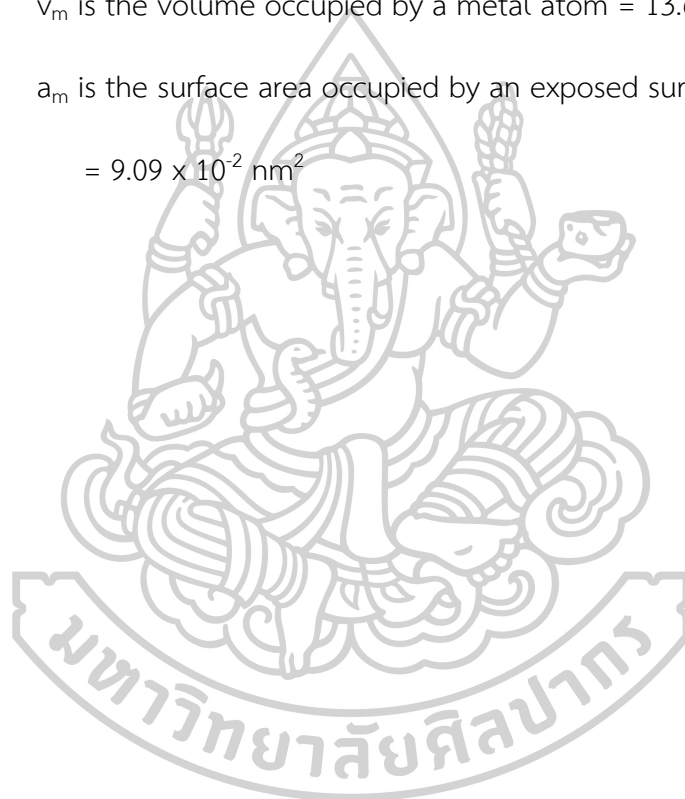

Metal particle size can be calculated by equation reported by Shen X. et al. [69] that followed in Eq. (C.3).

$$\text{Metal particle size} = \frac{6v_m}{\% \text{metal dispersion} \times a_m} \quad (\text{C.3})$$

Where v_m is the volume occupied by a metal atom = $13.65 \times 10^{-3} \text{ nm}^3$ for Ru

a_m is the surface area occupied by an exposed surface metal atom

$$= 9.09 \times 10^{-2} \text{ nm}^2$$

APPENDIX D
CALCULATION OF CO₂ CONVERSION, CH₄ SELECTIVITY, CH₄ YIELD,
CH₄ FORMATION RATE AND TOF

Composition of outlet gases mixture in reaction test is measured by GC-TCD equipment which it reports as area of species' peak. The calibration curves of species observed in this research are shown in **Figure 75 – 77**.

Figure 75 Calibration curve of CO₂ peak measured by GC-TCD.

Figure 76 Calibration curve of CH₄ peak measured by GC-TCD.

Figure 77 Calibration curve of CO peak measured by GC-TCD.

D.1 Calculation of CO₂ conversion

CO₂ conversion can be calculated by Eq. (D.1).

$$\text{CO}_2 \text{ conversion (\%)} = \frac{\text{Area of CO}_2 \text{ inlet peak} - \text{Area of CO}_2 \text{ outlet peak}}{\text{Area of inlet CO}_2 \text{ peak}} \times 100 \quad (\text{D.1})$$

D.2 Calculation of CH₄ selectivity

CH₄ selectivity can be calculated by Eq. (D.2).

$$\text{CH}_4 \text{ selectivity (\%)} = \frac{\text{Area of CH}_4 \text{ peak}}{\text{Area of CH}_4 \text{ peak} + \text{Area of CO peak}} \times 100 \quad (\text{D.2})$$

D.3 Calculation of CH₄ yield

CH₄ yield can be calculated by Eq. (D.3).

$$\text{CH}_4 \text{ yield (\%)} = \text{CH}_4 \text{ selectivity} \times \text{CO}_2 \text{ conversion} \quad (\text{D.3})$$

D.4 Calculation of CH₄ formation rate

CH₄ formation rate can be calculated by Eq. (D.4).

$$\text{CH}_4 \text{ formation rate (moles/g}_{\text{cat.}} \cdot \text{time)} = \frac{\text{Molar flow rate of CO}_2 \text{ inlet} \times \text{CO}_2 \text{ conversion}}{\text{Weight of catalyst}} \times \text{CH}_4 \text{ selectivity} \quad (\text{D.4})$$

D.5 Calculation of turnover frequency (TOF)

Turnover frequency (TOF) can be calculated by Eq. (D.5).

$$\text{TOF (time}^{-1}\text{)} = \frac{\text{Molar flow rate of CO}_2 \text{ inlet} \times \text{CO}_2 \text{ conversion}}{\text{Active site} \times \text{Weight of catalyst}} \quad (\text{D.5})$$
